The services of the following commissioned Medical Officers are replaced at the disposal of the Government of India, Home Department:—Surgeon-Captains Vaughan, Clarkson, Deare, Oldham, and C. R. Stevens. The services of Surgeon-Lieutenant Gwyther are replaced at the disposal of the Government of India in the Home Department. The services of the under-mentioned officers are replaced temporarily at the disposal of the Military Department:—Surgeon-Captain Dewes (Madras), Surgeon-Captain Kanta Prasad (Bengal), and Surgeon-Captain Williams (Bengal). The services of Brigade-Surgeon-Lieutenant-Colonel Little (Madras), Sanitary Commissioner, Hyderabad Assigned Districts, are placed temporarily at the disposal of the Foreign Department. To be Lieutenant:—Second Lieutenant Ivan Urmston Battye. To be Brigade-Surgeon-Lieutenant-Colonel:—Adam Scott Reid, vice Brigade-Surgeon-Lieutenant-Colonel C. J. W. Meadows, retired.

NAVAL MEDICAL SERVICE.

Deputy-Inspector-General of Hospitals and Fleets Belgrave Ninnis is placed on the Retired List, with permission to assume the rank of Inspector-General of Hospitals and Fleets.

VOLUNTEER CORPS.

Artillery: 7th Lancashire (the Manchester Artillery): Surgeon-Captain D. Macneilage resigns his commission. *Royal Engineers:* 1st Lancashire: Surgeon-Captain E. Williams to be Surgeon-Major. *Rifle:* 2nd Volunteer Battalion the Royal Warwickshire Regiment: Surgeon-Captain W. G. Creswell resigns his commission. Galloway: Surgeon-Lieutenant N. J. McKie resigns his commission. 2nd Volunteer Battalion the Welsh Regiment: David Llewelyn Davies, M.B., to be Surgeon-Lieutenant.

Digitized by Google

VOLUNTEER MEDICAL STAFF CORPS.

The Aberdeen Company: Surgeon-Lieutenant C. T. D. Urquhart to be Surgeon-Captain.

THE FIGHTING IN THE TOCHI VALLEY.

The official despatches, consisting of the General Order of the Military Department at Simla on the late field operations at Tochi, together with the military reports thereon from the officer commanding the Tochi Valley troops, having been received by the Secretary of State from the Government of India, have now been published in the *London Gazette* of the 7th instant. The force was a small one, forming the political officer's escort, and an attack was made on it by Madda Khels at Maizar on June 10th last. The circumstances under which this treacherous attack occurred are clearly set forth, and they show that it could not have been foreseen or guarded against, and was not in any way attributable to any negligence on the part of the troops, who were, under the circumstances, compelled to withdraw under exceptionally trying conditions. While we have to deplore the loss of a number of officers and men the despatches will be read with a glow of enthusiastic satisfaction at the great heroism and gallantry, coolness and discipline, displayed by the British officers, the native officers and troops, and all concerned. His Excellency, the Commander-in-Chief in India, submits that this record of a gallant deed of arms is second to none in the annals of the Indian army—a view in which the Governor-General in Council entirely concurs. The conduct of both officers and men on this trying occasion was, it is declared, worthy of the best traditions of the Punjab Frontier Force. No one reading the plain and graphic description of what took place can hesitate to admire the heroic and devoted conduct of the British and other officers in continuing at their posts and work in spite of their wounds. Surgeon-Captain Cassidy was one of the officers wounded on the occasion. Not only was the retreat most deliberately conducted, but the succour and care of the wounded were apparently admirably carried out under very difficult and dangerous conditions.

THE INDIAN RISING.

We have elsewhere alluded to the rising of the tribes on the Indian frontier. The punitive brigades are advancing, and the latest news indicates that the revolt of the tribes is collapsing rather than extending. A number of them are surrendering their arms, the Mullahs are losing their influence, and the news seems altogether more satisfactory than it was a week ago. The European force in India is being strengthened by troops and reinforcements from this country. The following officers of the Army Medical Staff have received orders to proceed to India for duty: Surgeon-Lieutenant-Colonel J. M. Beamish, Surgeon-Major J. S. Green, Surgeon-Major W. B. C. Deeble, Surgeon-Major W. Dugdale, and Surgeon-Captain D. Hennessy.

A NEW NAVAL ANNUAL.

Messrs. Witherby and Co. announce that they will issue in October next a new work entitled "The Royal Navy List Diary and Naval Handbook." The book will contain upwards of 500 pages, and, independently of the Diary portion, there will be a mass of matter touching upon all subjects of interest to naval men, and specially designed for the use of the service afloat and ashore. This should be a useful addition to the excellent "Royal Navy List" issued by the same publishers.

The Japanese are an up-to-date people, for we are informed, says the *Army and Navy Gazette*, that the Japanese Red Cross Society is going to build, at a cost of 1,000,000 yen, two vessels of 2600 tons each for the use of patients in time of war.

THE ROYAL PHOTOGRAPHIC SOCIETY.—We are informed that the forty-second annual exhibition of the Royal Photographic Society will be opened to the public at the Gallery of the Royal Society of Painters in Water Colours, 5A, Pall Mall East, on Monday, Sept. 27th. The exhibition will be open daily from 10 A.M. to 5 P.M., and on Monday, Wednesday, and Saturday evenings (when lantern slides will be shown) from 7 to 10 P.M. The exhibition will close on Nov. 13th. On Saturday, Sept. 25th, there will be a private view of the exhibits, followed in the evening by a conversazione, at which the President (the Earl of Crawford) and the Council will receive the Fellows, members, and their friends.

"Audi alteram partem."

"TRACHEAL INJECTIONS."

To the Editors of THE LANCET.

SIRS,—With reference to Dr. Thompson's paper on the above subject, published in the *Journal of the American Medical Association*, and to a leading article in THE LANCET of Sept. 4th, may I be permitted to point out that most, if not all, of Dr. Thompson's arguments have been anticipated in my paper, published in the Transactions of the Royal Medical and Chirurgical Society, vol. lxxviii. (1894). Shortly after a *résumé* of this paper was published in THE LANCET[1] I received scores of letters from "America" asking for further particulars, &c. Yet it now comes back as a sort of novelty. There are two points, the one in Dr. Thompson's paper, the other in the leading article, to which I would like to refer.

Dr. Thompson says the vehicle used should be light petroleum oil or olive oil. May I quote myself on this point?

"Observation of this case first suggested to me that olive oil was *not* the best vehicle in which to convey the medicinal agent to the lung. A demonstration of this was easy. I collected some of the dense expectoration from the case in a tube, closed with a cork at one end, and poured some of the oily solution on to it; after twenty-four hours the oil still remained at the top, whilst the lower stratum (which could be smelt by removing the cork) did not appear to contain either menthol or guaiacol. [The case referred to was one of bronchiecstasis.] It is all very well to demonstrate, as Sehrwald and Reichert have done, that the injected material can be found all through the lung tissues after an injection. So could it be found in the bladder. A few minutes after an intra-tracheal injection of turpentine I have noticed the characteristic smell of violets in the urine. The simple tube experiment mentioned suggests that the finding of menthol in the bronchioles, &c., after the injection of an oily solution (not miscible with the bronchial secretions) is more probably due to a secondary effort at *excretion* (subsequent to absorption) so easily noticed in the kidneys; and this, although very probably beneficial, is, I take it, quite different from bringing the original strong solution into *direct contact* with the diseased parts."

As regards your doubt as to the absorption of the drugs by the lung tissue, I will make a simple statement and ask an answer. I inject into the *tracheæ* of patients each week over one quart of fluid. If it be not absorbed what becomes of it?

I am, Sirs, yours faithfully,

Uppermill, Saddleworth, Sept. 8th, 1897. COLIN CAMPBELL.

THE INCREASE OF DIPHTHERIA.

To the Editors of THE LANCET.

SIRS,—I exceedingly regret to learn from THE LANCET of the still continued increase of this horrible disease, and have long thought it is due to the unsound condition of street sewers, the evil being increased on the "combined" systems. If I am right, then, there is no wonder at the steady increase, notwithstanding improved sanitary condition of houses generally. For some few years past it has been an acknowledged fact that the "chemical" and "smoke" tests are not always to be relied upon in detecting any leakage or unsoundness of drains under residences, and at the present moment I know of a vestry which refuses to use the only reliable test—viz., water—in such cases, even where the vestry has been assured of the unsoundness of a drain and the inmates suffering from the effect of the unsoundness. If authorities are so powerless with house-drains, then one cannot be surprised if the public sewers are in such a leaky and unsound condition generally.

I am, Sirs, yours faithfully,

London, Aug. 16th, 1897. D. T. BOSTEL.

"BATTEY'S OPERATION."

To the Editors of THE LANCET.

SIRS,—Dr. Kenneth Watson's letter in THE LANCET of Sept. 4th, 1897, introduces a subject which in these days of family limitation is frequently brought to the notice of the physician. A husband and wife desirous, for varying motives, of having no more children, and yet not wishing to lead single lives, agree to adopt some

[1] THE LANCET, Dec. 1st, 1894, p. 1270.

Digitized by Google

more or less harmful method of prevention. In spite of this conception occurs, and a medical man is consulted with a view to inducing abortion. The description given of the ill-health or sufferings of the patient during her last pregnancy and confinement is sure to be an exaggerated one, and the truth can only be estimated by tactful inquiries, which elicit an evident determination to have no more children—a resolve founded usually upon notions of economy. At such an interview one is lead to realise that if this same patient were endowed with a strong maternal instinct, and was keenly desirous of having a living child, the previous one having been stillborn, all these considerations would be made very light of. Unless there is a strong professional reason why another pregnancy or confinement should be prohibited the physician should listen to no social or domestic arguments, and should refuse to countenance any operation which would tend to prevent conception or to terminate an existing gestation.

In Dr. Kenneth Watson's case the first labour was tedious, and was terminated by forceps. It was accompanied by hæmorrhage and a severe perineal rupture. The second labour was unaided and very rapid, and the perineum was again partially ruptured. These conditions might, perhaps, in the opinion of some, be considered indications for inducing premature labour two or three weeks before full term, but would not, in my opinion, warrant a medical man advising either total sexual abstinence, the adoption of preventive methods, or any sterilising operation.

To advise a woman to have her healthy appendages removed for a moderate contraction of the bony pelvis or of the soft parts is never justifiable, for in these days of antiseptic midwifery a premature labour can be easily and safely induced at the appropriate date, and the child, if properly tended, in no way suffers. If the contraction be so marked that Cæsarean section has to be performed the patient may then easily be rendered sterile without extra risk, though even this is not essential. If an extreme degree of pelvic contraction exist, and is only discovered after conception, and it is evident that a viable child cannot be borne, and the risk of a Cæsarean section is dreaded, abortion should be induced; but I doubt whether it would ever be justifiable to castrate the woman even then—it would be a proceeding which would be so likely to be abused that it is to be hoped it will not be advocated. If ever such a course were indicated, apart from Cæsarean section, I should prefer the vaginal rather than the abdominal method. In these respects, I fancy, Dr. Watson's views do not materially differ from my own.

May I correct one statement which Dr. Watson seems to make? Removal of healthy ovaries is *not* "a recognised procedure in certain neuroses, such as hystero-epilepsy." This was Dr. Battey's original dictum, but oöphorectomy, for the treatment of neuroses, has now been discontinued owing to its almost uniform failure to cure.

I am, Sirs, yours faithfully,

Manchester-square, W., Sept. 6th 1897. AMAND ROUTH.

"THE EMPLOYMENT OF GLOVES IN SURGERY."

To the Editors of THE LANCET.

SIRS,—The note in your last issue on the use of gloves in surgery as recommended by Mikulicz and von Manteuffel causes me to beg space for a few observations. I have not in surgical work found evidence of any insuperable difficulty in rendering the hands sterile, but in septic surgical cases there is danger both to the operator and to his other patients. For such cases I now use the same kind of gloves that I have described and recommended in my small work on "Post Mortems." Since the publication of that work last year I have had from time to time inquiries as to exactly the kind of glove I recommend. At my request Messrs. Mayer and Meltzer, 71, Great Portland-street, have laid in a stock of the gloves so that medical men may be able to obtain them without delay. Of course different pairs of gloves must be used for post-mortem and for surgical work, and they should be kept in separate bags and distinct from the bag used for the apron, &c., worn in operating on aseptic cases. Before removing the gloves they should be washed with soap and rinsed first in water and then with carbolic lotion.

I am, Sirs, yours faithfully,

Old Cavendish-street, W. J. JACKSON CLARKE.

POLICE FEES AND THE MEDICAL PROFESSION: AN APPEAL TO THE LARGE TOWNS.

To the Editors of THE LANCET.

SIRS,—In consequence of the irregularity in the charges made by medical men the watch committees of several towns have laid down certain scales of fees which they undertake to pay for ordinary attendance when the assistance of the medical man is sought for by the police. In Newcastle-upon-Tyne the scale is 3*s.* for day and 5*s.* for night visits; in Plymouth 3*s.* 6*d.* and 7*s.* 6*d.*; in Bradford 7*s.* 6*d.* for both day and night; in Stockport 3*s.* 6*d.* and 5*s* 6*d.*; in Cardiff 3*s.* 6*d.* and 7*s.* 6*d.*; in Exeter 3*s.* 6*d.* and 7*s.*; in Liverpool 3*s.* 6*d.* between 7 A.M. and 11 P.M., and 7*s.* 6*d.* between 11 P.M. and 7 A.M.; whilst in London it is 3*s.* 6*d* for day and 7*s.* 6*d.* for night visits. In Portsmouth it has been recently fixed at 3*s.* 6*d.* from 8 A.M. to 10 P.M., and 7*s.* 6*d.* from 10 P.M. to 8 A.M.

It must be borne in mind that these fees were primarily made in many towns to govern payment to the police surgeons, who are called to every possible case. Having so many cases the remuneration was considered sufficient. In the case of general practitioners—who are only called in occasionally, and then only to cases of great urgency when there is no time to send for the regular police surgeon—the fees are totally inadequate. The medical profession in Portsmouth, through its Medical Union, has asked the Watch Committee for payment on the following scale:—

For a visit between 8 A.M. and 8 P.M. ...	Five shillings.
For a visit between 8 P.M. and midnight	Seven shillings and sixpence.
For a visit between midnight and 8 A.M.	Ten shillings.

The grounds upon which the Portsmouth Medical Union based its request were as follows:—1. Calls to police cases are always urgent and require immediate attention; consequently other work has to be suddenly suspended. 2. These cases are most frequently serious, and involve prolonged attendance, as the police do not apply for help in trivial cases or when there is time to send for the regular police surgeon. 3. Very particular attention has to be given to every possible detail of each case, in view of subsequent legal proceedings. This demands extra time in addition to the extra mental strain involved.

Notwithstanding these explanations the Corporation of Portsmouth have refused to accede to the tariff of the Medical Union. In considering this question it has to be borne in mind that these are not the fees of a public medical service, but only for occasional and urgent cases to which the police require our assistance. How many calls not made by the police to street accidents and sudden illness medical practitioners receive without ever getting the slightest remuneration only the medical profession is aware of? If these cases were paid for by the police where the fees were not obtained from the patient, the scale adopted by the various corporations would be acceptable to the medical profession. It cannot be said that 3*s.* 6*d.* is an adequate payment for a sudden call to a police case, although it might be for the less serious street cases to which every practitioner is now and then summoned.

It would seem as if the corporations in their illiberal treatment of professional men had taken advantage of the moral reprobation in public opinion which would follow refusal on the part of a medical man to attend when summoned by the police. Not only public opinion, but feelings of humanity, prompt us to render assistance whenever we are called, whether there be any prospect of remuneration or not; so that for a public body to pay us inadequately for our services under these circumstances is, to say the least, mean in the extreme. It is comparable to being stingy in remuneration to a lifeboat's crew after attendance at a shipwreck, although, if we do not always risk our lives, we might be otherwise, often much more profitably, employed. Portsmouth will have to fight its battle for itself, but I wish to ask the medical men in the towns above mentioned to rebel against the low scale of fees allowed them in these cases and individually, as well as collectively, to notify their watch committees that in future they will require payment on the higher scale. In the event of refusal there is the resort to the county court. Success here, however, much depends upon the sympathies of the presiding judge, and also as to whether the doctor's case is properly laid before him. It seems, at any rate probable, that if a medical man had notified the watch committee of his scale of fees and they were reasonable the committee would be compelled

Digitized by Google

to pay. Combination of the profession in each town ought to do a great deal in this matter, as evidence in support of a given case should be easily obtainable. Special cases requiring special services must, of course, be considered on their individual merits. It is sufficient for us now to adopt some uniform scale for ordinary visits. I therefore recommend the above scale of fees of the Portsmouth Medical Union as the most equitable that has been suggested, and would urge upon practitioners in every town to demand payment upon this scale.

I am, Sirs, yours faithfully,

T. FREDERICK PEARSE, M.D.,
Sept. 4th, 1897. Hon. Sec. Portsmouth Medical Union.

"IMMORALITY AMONG SCHOOL BOYS."

To the Editors of THE LANCET.

SIRS,—I have read with great care and interest Mr. Hime's article on the above subject, and whilst fully recognising that the vice to which he refers exists to a large extent, and that it is the duty of all concerned in the rearing of boys (not of head masters only, by the way) to do everything in their power to check it, I cannot for one moment agree with him as to the best means of preventing such habits. He divides these methods into two classes: (*a*) school arrangements; and (*b*) moral suasion. Of the latter of these I have not much to say, except that a few veiled remarks on the subject in the form of a lecture to a body of school boys do not strike me as likely to do much good. Much more to the point is the advice and warning given by him to each new boy on his arrival at school. It is with the school arrangements for preventing immorality that I have to quarrel, for, in brief, what do they amount to? Nothing more or less than a system of continual spying on the boys night and day, during playing and during working hours, without intermission; they are never allowed to be alone. This is a system calculated to bring out all that is underhanded, vicious, and deceitful in a boy, and to repress all that is above-board and honourable. This was not the plan of Dr. Arnold, the greatest of head masters; it approximates too closely to the French system of education to be agreeable to the majority of Englishmen. If, as Mr. Hime claims, "the companionship [during play hours] of a suitable master was always agreeable to the boys," then he must, indeed, have met with a curious collection of them; there is not one other like them in England. Boys, like everyone else, want to be free from restraint occasionally, and this is impossible with Mr. Hime's method of a master's bedroom opening out of each dormitory, with a master always superintending studies during school hours, and with a master always attached to the boys at play. Without going fully into the treatment of this habit I might call your attention to the old classical remedy—plenty of healthy exercise and not too much animal food—and suggest that these are the lines to go on to arrest the immorality of boys, not those of Mr. Hime.

I am, Sirs, yours faithfully,

L. A. PARRY, M.D., B S. Lond., F.R.C.S. Eng.
Bartholomew-road, N.W., Sept. 6th, 1897.

THE HOSPITAL REFORM ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—I have much pleasure in informing you that the Earl of Stamford has kindly consented to preside at our conference on Oct. 21st. This will prove a source of gratification to all who are interested in the subjects we propose to discuss, as it is well known that his lordship has devoted much time and attention to the administration of hospitals. My council would like to suggest that the subject of out-patient administration should be dealt with under the following heads: (1) from a consultant's point of view, (2) from a general practitioner's point of view, (3) from an administrative point of view, and (4) from a patient's point of view.

In order that an expression of opinion may be obtained from as many gentlemen as possible it has been decided to make a time limit for readers of papers and speakers, and fifteen minutes for the former and five minutes for the latter have been fixed. Priority will be given to those gentlemen who have announced beforehand their intention of speaking.

I am, Sirs, your obedient servant,

Cardiff, Sept. 7th, 1897. T. GARRETT HORDER, Hon. Sec.

HEALTH QUESTIONS AT THE ZURICH INTERNATIONAL CONGRESS FOR THE PROTECTION OF LABOUR.

(FROM A SPECIAL CORRESPONDENT.)

A REMARKABLE and, in one sense, an unprecedented Congress has been held at Zürich. THE LANCET, of course, is in no wise concerned with the political aspect of this Congress; but the desire manifested by the members to assimilate internationally laws framed so as to protect the health of the working community of all civilised countries involves many questions in which your readers take a deep sympathetic interest. Undoubtedly one of the most effective arguments against legal restrictions upon unwholesome industries, nightwork, and the hours of labour generally is the danger of foreign competition. On the other hand, if similar laws were simultaneously enacted by other countries this danger might be reduced to a minimum. Such was precisely the aim and purpose of the Congress in question. But it does not suffice to merely express a good sentiment or to make advantageous proposals. Ideal reforms are more readily conceived than realised. The practical point depends on the force of the organisations which adhere to these proposed measures. Therefore it is necessary to say a few words as to the political elements which composed the Congress, not for the sake of dealing with politics, but so as to show that the Congress constituted a demonstration of sufficient importance to have some influence on European governments—an influence which will tend towards the improvement of public health. In advocacy of such restrictions on the freedom of labour as may be necessary to preserve the health of the workers there have been innumerable congresses, both national and international, composed of medical men, of sanitary reformers, and of philanthropists. Nor have the workmen themselves been indifferent to their own interests. The annual congresses of the trades unions of Great Britain invariably adopt a number of resolutions demanding better legislation for the protection of the health of the workers. Resolutions to the same effect are likewise discussed and approved at the political gatherings, national or international, of the working class or labour parties. But when such congresses have been representative congresses—that is to say, when they were composed exclusively of delegates elected by organised bodies—they were purely party gatherings. The Zürich Congress, on the other hand, may be qualified as unprecedented because, though composed of the elected representatives of constituted associations, it was not a party congress, but, on the contrary, brought together men belonging to antagonistic parties, who up till now have waged bitter war against each other. There were 375 delegates, representing fifteen different nationalities; of these, 107 were elected by Roman Catholic working-men's associations, some of these being priests, who, like the Belgian Abbé Daens, have acquired a wide reputation for their advocacy of the poor and oppressed. The Evangelical or Protestant associations sent only a few representatives. The other delegates were either trade unionists or members of political socialist organisations. There were also a considerable number of members of the Belgian, Swiss, Italian, Austrian, and German Parliaments, belonging some to the Socialists and some to the Roman Catholic parties. The chair was occupied alternately by M. Sherrer, a leading Swiss social democrat, and by M. Decurtius, leader of the Roman Catholic party in the Swiss National Council or Federal Parliament. Throughout the greatest order was maintained; most of the resolutions were carried unanimously, and in dealing with the need of international legislation for the protection of labour these old and inveterate adversaries forgot their differences and worked throughout harmoniously and amicably, and this, too, in spite of the trying fact that the Congress sat during eight hours a day for an entire week. That such heterogeneous elements should thus have been brought together shows that the demands made are widely appoved and not confined to one single faction or party, but are supported by both orthodox and heterodox organisations existing in no less than fifteen different countries. Therefore, there can be no doubt but that the Congress will

Digitized by Google

exercise some influence on the legislatures of different countries. Consequently, it is of some importance to ascertain what was said and done with regard to the preservation of public health.

The first day was devoted to the question of Sunday rest. Professor Joseph Beck, Doctor of Divinity, of Fribourg, presented a report on this topic. In his opinion the fact that in England there is a lower death-rate than on the Continent was in a measure due to the better observance of the weekly rest. The Swiss law insists that railway servants should have fifty-two days' rest per annum, comprising every third Sunday, or seventeen Sundays in the year. He showed that when the French Revolution tried to establish the *décadi*, or every tenth day, as a holiday this was found insufficient, and after two years' time the weekly holiday had to be restored by the law of Aug. 2nd, 1799. But for the Sunday to be a real day of rest it was necessary that work should cease early on Saturday, so that all domestic work could be done on that day. The Congress was unanimous in demanding thirty-six consecutive hours of rest per week. But it was also unanimous in demanding that traffic should not be stopped, and that all which contributed to the intellectual development or the recreation of the people on Sundays should be sanctioned. The mind as well as the body required a holiday, and this could not be provided during a day of stagnation and dulness. The British delegation were loud in their protest against the dreariness of the English, and more especially the Scotch, Sunday, and maintained that the sole alternative of church or public-house did not constitute a healthy holiday either for the mind or the body. This view was fully endorsed by the Continental delegates. At the same time, the resolution carried made full provision assuring that those who, to meet these views, had to work on Sundays should have a rest of equal duration during another part of the week.

The second day was occupied in the consideration of a report presented by Dr. F. Gehrig, of Berne, on the work of children and young persons. He pertinently inquired why Governments thought young men were not fit for military service till they reached the age of twenty years, and yet allowed them to do what was often equally hard work in factories or mines when they were much younger. Dealing with the medical aspect of the case, he insisted more especially on the derangements produced in the nervous system, and, as a consequence, on the organs of digestion and nutrition. The "pyschosis of overwork" was to be noted among young and too ardent students, but it was more marked among youths who were overstrained by physical work. Among young persons who had to stand for many hours varicose veins, hæmorrhoids, and ulcers were of frequent occurrence. The carrying of heavy weights dilated the heart and produced the well-known X or "factory legs." Flat-feet and hernias had often the same origin. He then pointed to the contrast between the elaborate care taken in good schools to vary the occupations of children, to give them good air, light, and plenty of exercise, and the monotonous nature of the work done in the close, dusty, and often damp atmosphere of a factory. The Congress voted that children should not be allowed to work till they were fifteen years of age, and then only five days a week of eight hours each day till such time as they had reached the age of eighteen years.

On the third day M. Otto Lang, judge of the tribunal of the Zürich district, presented a report on the work of adult males. He pointed out that in several countries, notably Austria, France, and Switzerland, a maximum labour day for adults had been established by law, and this varied from eleven to twelve hours. Of course, women and children have the greatest need of such protection, but men may also overwork themselves. He complained of the attitude of the British Government. The Swiss Government, by its circular of Jan. 28th, 1890, had invited the nations of Europe to an international conference on labour protection, but the British Government refused to participate if the labour of adults was to be included in the subjects of discussion. It was also at the instance of Great Britain that this question was effaced from the programme of the Labour Conference convoked at Berlin in March, 1890, by the German Emperor, yet no authority had been more liberal in the reduction of the hours of labour in State factories, arsenals, &c., than the British Government. The Congress voted in favour of the eight-hours' day, though many speakers admitted that in the lighter occupations adult males could work more than eight hours without physical injury. It was from the moral rather than the physical point of view that the eight hours' legal limit was approved. The clerical element in the Congress was particularly anxious to restore family life which long hours of absence in the factory or workshop tended to destroy. This feeling was very forcibly manifested when on the following day the question of women's work was introduced by M. Jean Sigg, member of the Geneva Cantonal Parliament. He quoted with great effect the report of Dr. Schuler, Swiss Inspector of Factories, who showed that in his particular district the mortality of newly-born infants amounted to from 29 to 30 per cent. of the births, but that this mortality had been reduced to the extent of 5 per cent. by the law which forbids women returning to work till six weeks after their confinement. Among the textile workers of Ghent, on the other hand, the mortality of children, which amounted in 1886 to 452 per 1000, was equal to 482 in 1888, 620 in 1889, and 630 in 1890. More recent figures were not at hand, nor was any explanation given as to whether an epidemic prevailed during the last two years mentioned. But in any case it is evident that the mortality is excessive. On this phase of the question there was no difference of opinion, and the Congress unanimously voted that women should not be allowed to work till six weeks after their confinement. It was also thought that if legislatures should, as suggested in the former resolution, tend towards the reduction of the week's work to forty-eight hours for men, it should not exceed forty-four hours for women, and that women should not work more than eight hours on any one day. The Roman Catholics wanted to gradually but altogether abolish the work of women in factories. All these points were discussed on social, economical, ethical, and political grounds, but they were also related to the sanitary or health point of view. A woman who exhausted herself in factory work could not be a true mother to her children, and their health would consequently suffer. The British delegates, on the contrary, maintained that the work of women in factories was in any case less likely to be excessive and unwholesome than their work in small workshops or in their private homes. They proposed, not the abolition of factory work, but of home work. Neither party carried their point. By a large majority the Congress refused to vote in favour of abolishing women's work in factories, and it decided to refer the question of home work to a future congress. In the course of the discussion on the latter subject Miss Sullivan, of the London West-end Tailoresses Association, referred to many of the abuses denounced by THE LANCET in the course of its numerous Special Reports on the Sweating System.

On the fifth day Dr. F. Erismann, formerly Professor of Hygiene at the Moscow University, introduced the question of night labour, which had only come into existence with the introduction of steam power and the development of modern industrialism. Machinery was so expensive that its owners wished to employ it day and night, and it was only when the health of vast populations had been seriously injured that legislation interfered to protect, at least, the women and children. So far back as the year 1815 the Canton of Zürich forbade the night work of children in factories. This abuse was allowed to continue in England till 1834, and the measures taken were not thoroughly effective till some years after. After reviewing the laws of various countries Professor Erismann mentioned the German law of 1891 by which adult women are not allowed to work after 8.30 P.M. and before 5.30 A.M. Nowhere, except in Switzerland, do the laws absolutely abolish night work for all persons under eighteen years of age. Such work is only restricted, exceptions are made, and in Germany there are no less than 2 000.000 factory hands who are liable to be called upon to do night work. Generally speaking, permissions for night work are too freely granted. The injury that results from night work is more readily proved by the benefits that have followed its abolition. When men had worked during their childhood in factories they became incapacitated for work early in life. Out of 22,094 Manchester workmen only 143 were found to have passed their forty-fifth year. On the other hand, when a check was placed on the excessive work of women and children in England it was proved that the weight of newly-born infants among the factory population greatly increased. The Zemstrov, or County Council of Moscow, has officially reported that among the cotton-spinners of their district a great physical deterioration has taken place, and many of the men are rendered unfit for military service. The mills run the whole twenty-four hours. There are two shifts, which work six hours each, or twelve hours a day, and therefore the men can never sleep much more

Digitized by Google

than five hours at a time. But even if sufficient sleep could be obtained during the day the nervous system is bound to suffer from taking rest at unnatural times. Thus, in Alsace-Lorraine, though among the wool-weavers the night hands worked 22 per cent. less time than the day hands, it was found, in 1888 and 1889, that there were 328 and 309 cases of illness per 1000 workwomen during 5641 and 5815 days where no night work was done. In other mills, where there was only partial night work, there were 429 and 413 cases of illness during 8730 and 8865 days of work for every 1000 workwomen employed. With regard to adult males Professor Erismann had no hesitation in saying that night work was also injurious to them, should be suppressed wherever possible, and only sanctioned in exceptional cases, and then it should not last longer than eight hours, and must be followed by sixteen hours' rest. Dealing next with unwholesome industries, statistics compiled by Hirt showed that out of 100 workmen who became ill from breathing the dust of factories, &c., from 13·3 to 18·0, according to the industry, became consumptive; whereas among those who worked in pure air, out of 100 cases of sickness only 11·1 developed phthisis. Where the dust contains some poisonous chemicals the injury done is of course much greater. At least 40 per cent. of the cotton-spinners who die in the hospitals of Russia die from chronic lung-disease. Speaking of mill-stone makers Professor Erismann said that the "sand contained in the lungs of adults was equal to 7 per cent. of the whole; with stone-cutters it amounted to from 23 to 24 per cent.; and, according to Meinel, was equal to 30·7 per cent. among glass-polishers. According to Lewin, the mortality from tuberculosis amounted to 8·25 per cent. among stone-cutters, and their average age was only twenty-four years. The researches made by Sommerfeld set forth that 90 per cent. of the stone-workers die from phthisis of the larynx, of the lungs, or chronic catarrh. Out of 187 stone-workers 25 per cent. had pulmonary phthisis, 7·9 per cent. phthisis of the larynx, and 66·6 per cent. chronic catarrh of the larynx." Thus were the various leading industries passed in review one after the other. Then a synopsis of the laws affecting them in the different countries was likewise given.

It was after thus examining a great mass of information that the Congress voted in favour of the total suppression of night labour for women and young persons, and defined the night as lasting from eight in the evening till six in the morning. It was acknowledged that for men in exceptional cases night labour must be allowed, but must never exceed eight hours in the twenty-four. Dangerous or unwholesome industries should, according to the resolutions carried, be very carefully specified and tabulated in the text of the law. Such industries should only be authorised when the fullest precautions have been applied. The employment of young persons under eighteen years must be absolutely forbidden. In dangerous industries the hours of labour must be shorter than in other occupations, and there ought to be periodical and official or governmental medical inspection of all the workpeople. The employment of poisonous substances wherever possible must be forbidden.

Of course, it will be said that all these demands, however estimable in themselves, are not practicable in the face of the exigencies of business. For this reason the Congress discussed on the sixth and last day the all-important question of ways and means. First, the Congress demanded that in every country a sufficient number of factory and workshop inspectors should be appointed to be able to visit every workplace at least twice in the year. This if costly is not an absolute impossibility. Then they demanded for the working-classes of all countries the fullest possible political freedom, so that they might not only influence legislature in the direction indicated, but form such trade and other societies as would see that laws were not merely enacted, but actually applied. Members of Parliament who sympathise with the objects of the Congress were invited to simultaneously present in their respective Parliaments similar projects of law. They were also to request their respective Governments to join in forming an international office for the protection of labour, where all information on the subject might be centralised and interchanged between the nationalities concerned.

Finally, the Swiss Government is asked to renew the effort it made in 1890 to bring about an international conference between representatives of the European Governments with the view of assimilating as far as possible the laws of the different countries which deal with the age at which young persons and children may work, the prevention of night labour, and the employment of women in dangerous occupations, Sunday rest, the maximum labour day, &c. Of course, the Congress was fully aware that the desiderata laid down in the resolutions was not to be realised in a day; but it felt that if in each country the various organisations, whether clerical or secular, that had these ends in view were to unite instead of quarrelling with each other, something effective would be much more easily accomplished. It would then be more difficult for legislators to neglect these questions, and in the face of such a manifest desire for an international understanding a good deal might be done to mitigate the danger of foreign competition when such reforms were introduced. If the movement follows faithfully these lines there is some chance that a portion, though probably only a small portion, of the measures demanded will be granted at no very distant future. In that case, and however fragmentary such improvements may be, there is little doubt but that they will tend towards an amelioration of public health. Under these circumstances this new and conjoint movement of parties and organisations which on so many other subjects are hostile to each other cannot fail to interest the members of a profession which is so intimately concerned with all that relates to the health of the people.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The High Death-rate.

CONSIDERABLE anxiety has been felt in the city owing to the unusually high death-rate in the last few weeks, reaching as much as 43 per 1000. Various causes have been alleged as the reason for this. Diarrhœa has claimed the greatest number of victims, but with this exception, and that of measles, the zymotic diseases have not appreciably increased the roll; 75 per cent. of the deaths from diarrhœa are in children under a year old. Many believe that defective sewage arrangements are the main cause of this, but the medical officer of health, Dr. Hill, points out that in the month of June, when the sewers had to be flushed without rainfall, the death-rate was very low and there was but little diarrhœa. Many complaints have been made about the sewers, and no doubt the population has increased enormously since these were laid down. At present an inspection is being made by the authorities, who will issue reports as the work proceeds. There are about 260 miles of sewers, so necessarily this overhauling will take some time. A great deal of surface water now runs into the sewers which it is beyond their capacity to carry off. Some means are proposed to divert this and thus limit the work they have to do. Some of the complainants go so far as to say that the town ought to be re-sewered, but the Health Committee point out that this would be a gigantic undertaking, involving many years' work and a probable cost of half a million of money. They are anxious to do all in their power to provide for efficiency, with a due regard to the various problems involved. In the meantime, it is satisfactory to know that the death-rate has been steadily diminishing from the high record noted.

King's Norton Workhouse Infirmary.

The new building at Selly Oak was formally opened on Sept. 3rd and is well calculated to meet the requirements of the population for some time to come. The total cost is estimated at about £210 per bed, and there are now 418 inmates in the workhouse. At present the site is about fourteen acres, and there is a possibility of the number of beds being increased up to 500 in the future. Nothing has been spared in equipment and arrangements to make the building a complete one for the purposes required.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Culvert Scheme.

THE report of the deputation from the Mersey and Irwell Joint Committee to the Local Government Board, as given in THE LANCET of Aug. 14th, clearly foreshadows some relaxation of the Board's hard and fast line requiring the filtration

Digitized by Google

of sewage through land, and also its sanction, in suitable cases, of artificial filtration. Sir Henry Roscoe, in his dual capacity of adviser to the Joint-Committee and the Manchester Corporation, against whom his committee is carrying out proceedings, has warmly recommended precipitation and artificial filtration, which is said to give a satisfactory effluent at Salford. At the meeting of the Manchester City Council, on the 1st inst., Alderman McDougal, who is not without chemical knowledge, threw grave doubts on the lasting properties of the filters. At the works at Davyhulme, though still doing good work, they are doing less of it. "They were gradually becoming coated, there was less space for water in them, and in three or four years the filters would have to be renewed." It is interesting to note that since the admission of the out-townships to the sewerage system there has been a change in the character of the sewage matters from the large admixture of the effluent from chemical works. "According to the tests of the joint committee twice as much oxygen as before was being absorbed; they were not precipitating as well, and the effluent was worse." But "in Whit week, when they got only domestic sewage, the effluent would have satisfied every requirement of the joint committee." Still, Alderman McDougal holds that the Manchester effluent is a very fair one and if sent into a running stream would do no harm. Unfortunately it goes into the putrescent and practically stagnant water of the Ship Canal. The scheme for applying artificial filtration to the whole of the sewage is found on calculation to be so costly as to be almost impracticable. In addition to the cost of the extension of the filters, which would be almost as great as the construction of the culvert to tidal water, their maintenance would require annually from £30,000 to £40,000. The Council therefore has abandoned the filtration scheme, and has decided almost unanimously in favour of the construction of "a culvert between six and seven feet in diameter and about sixteen miles long from the works at Davyhulme to the estuary of the Mersey." In introducing the question Mr. Saxon stated that it "would convey the effluent after the sewage had been treated by precipitation, as they were treating it at present by chemical processes and precipitation tanks. A very clear effluent would be passed through the culvert." The estimate for this culvert is £258,000, not taking into account law costs and Parliamentary expenses. After giving various reasons—as urgency, &c.—for the scheme he adds a suggestive remark: "The greatest reason of all, however, was that it took the [Rivers] committee out of the jurisdiction of the Mersey and Irwell Joint Committee, and they were consequently freed from their excessive requirements as to purity." It does not appear that the sludge is to be sent down the culvert, so that it will probably be carried out to sea at considerable cost. Alderman Hopkinson said truly that the scheme might be called "a policy of despair," and it is opposed to the ideal of "the sewage to the land."

Sept. 7th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

More Suicides in Liverpool by Carbolic Acid Poisoning.

IN THE LANCET of Aug. 14th comment was made, in the case of a suicide through poisoning by carbolic acid, on the easy means afforded to the public of procuring that drug. During last week no less than three more deaths from the same cause took place in Liverpool, all of which were investigated by the city coroner. Four suicides from the effects of carbolic acid poisoning occurring within one month ought to be sufficient evidence of the danger of allowing it to be so easily obtained by the public at large. Possibly these lamentable occurrences may stimulate the legislature to place greater restrictions on the sale of carbolic acid. Since writing the above it has just come to my knowledge that last night a married woman was admitted to the Royal Southern Hospital suffering from the effects of carbolic acid, and died shortly afterwards.

Increased Accommodation at Rainhill Asylum.

The chairman of the West Derby Board of Guardians intimated at the last meeting that the Lancashire Asylums Board had agreed to provide two hundred additional beds at the County Asylum at Rainhill. By these means the pressure occasioned at the local workhouses by the difficulty of removal will be considerably relieved.

Prospective Closing of Intra-Mural Cemeteries.

The proceedings of the Health Committee at their last meeting contained a recommendation for application to Parliament for power to close St. Mary's Cemetery, Walton-road; the Necropolis; St. George's Churchyard, Everton; St. Mary's Churchyard, Edge-hill; St. Michael's Churchyard; and St. James's Churchyard, Toxteth. It will be remembered that these comprise a portion of the cemeteries which were unfavourably reported upon by the medical officer of health and the closing of which he strongly recommended.

Typhoid Fever and Sewer-polluted Shellfish at Waterloo.

A great number of cases of typhoid fever occurred last month in the Waterloo and Seaforth districts which, on investigation by the health authorities, were proved to be due in a great measure to eating mussels and cockles contaminated by sewage. The shellfish were collected by children from the foreshore, close to the outlet of the south sewers.

Sept. 7th.

WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Proposed Convalescent Home for Bristol.

MR. P. H. VAUGHAN has given £3000 to the proposed convalescent hospital for Bristol. The balance remaining to be collected is now £9500.

The Sewage of Bristol.

At a meeting of the Bristol Sanitary Committee, held on Aug. 26th, a communication was read from the Local Government Board calling attention to an application made by the local authority of Westbury-on-Trym with respect to a scheme in which it was proposed to pour the sewage of the place into the River Avon. The town clerk was instructed to inform the Local Government Board that the sanitary committee are now considering as to the best means of dealing with the sewage nuisance in the river. The chairman remarked that it would be a curious thing if, whilst considering how they could deal with the sewage nuisance in the river, they were to allow the Westbury sewage to be thrown into it.

The Epidemic of Typhoid Fever at Wadebridge.

At a meeting of the St. Columb Major District Council held last week a report was read from the *locum tenens* of the medical officer of health. It stated that the epidemic of typhoid fever at Wadebridge was caused by the deficient sanitary arrangements of that town; also that the water-supply, which is unfitted for the present requirements of Wadebridge, had been contaminated through the absence of a complete system of drainage and the unsuitable method of scavenging which is adopted. The report added that owing to the Infectious Diseases Notification Act not being enforced in the district three weeks had elapsed before the medical officer of health had knowledge of the outbreak, which had resulted in twenty-three cases, with two deaths.

Typhoid Fever Cases in the Swansea Hospital.

Two nurses from the Swansea General Hospital whilst nursing typhoid fever cases in Gower contracted the disease and were admitted into the Swansea Hospital. Some comments have occurred in the local press upon the subject, owing to the fact that enteric cases have not been admitted into this institution for several years, although in 1885 an unsuccessful effort was made to obtain permission for their treatment. It is difficult to see why the authorities of the Swansea General Hospital cannot follow the example of the majority of London and provincial hospitals and admit cases of typhoid fever.

Infectious Diseases Notification Act at Aberdare.

At the meeting of the Merthyr Tydvil board of guardians, held on August 28th, the Rev. Father O'Reilly moved that a representation be made to the Aberdare Urban District Council urging them to enforce the Infectious Diseases Notification Act. He said that in the opinion of the county medical officer of health it was essential that the Act should be adopted. The Rev. Father O'Reilly added that Aberdare was the only parish in Glamorganshire where the Act was not in force

Digitized by Google

and commented upon the danger arising from infectious diseases not being notified, stating that at present there were at least three suspicious cases of typhoid fever, and unless precautions were adopted the other inhabitants of the locality would be exposed to risk of infection. The chairman described the Act as unfair, because it provided for the infliction of penalties upon heads of families for failure to report. A division was taken, when twenty-one declared in favour of the motion, no one voting against it.

Sept. 7th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Lunacy in Scotland.

IN the thirty-ninth annual report of the General Board of Lunacy for Scotland, which was issued last week, the number of insane persons in Scotland on the first of January of the present year is stated to have been 14,500, of these 2217 were maintained from private sources, 12,221 by parochial rates and 62 at the expense of the State. During 1896, as compared with the previous year, there was a total increase of 383 registered lunatics. Pauper lunatics, under care for longer or shorter periods during the year, numbered in all 14,082. For these there was a total expenditure of £276,865; of this sum £115,761 was contributed from the local taxation account, and £13,403 was repaid by relatives and others. The average annual expenditure for each patient for the year 1895—1896 was £23 9*s.* 3*d.* The report draws attention at some length to the necessity for providing further accommodation for the poorer class of paying patient. There is at present in Scotland very little provision for that class of patients who are able to pay little or nothing beyond the cost of board for pauper lunatics. The Royal asylums are so much in demand for the wealthy class of patients that it is impossible for them to accommodate more than a small number of patients at the very low rates. The district lunacy boards in Scotland have no power to provide accommodation for private patients. In both England and Ireland, however, this permissive power is held by the district boards. In consequence of these conditions it commonly occurs that persons who are unable to pay the higher rates of board are compelled to apply for assistance to the parochial authorities. The parish council as a rule consents to the admission of the patient as a pauper *lunatic on* the condition that part or the whole of the board be repaid to the parish by the relatives of the patient. As, however, by this procedure the patient is pauperised—is on *exactly the* same level as ordinary paupers, in spite of the payment of money—the relatives, as a rule, gradually endeavour to rid themselves of the burden of payment which, *while* burdening them, is not improving the condition of the patient. The report, therefore, recommends that legislative procedure be taken to confer on the Scottish district lunacy boards a similar power to that held by the boards in the sister countries—the power of providing accommodation for private patients. It recommends that, in framing such a measure, the following principles be kept in view. "1. District lunacy boards should be authorised to receive private patients, and also to provide accommodation for such patients, if they should see fit, by erecting separate buildings or by setting apart for the purpose sections of existing buildings. 2. Private patients being once received should be regarded as having a right of accommodation, and should not be liable to be removed to make room for pauper patients. 3. The rate of board chargeable for maintenance should not be higher than the maintenance rate charged for pauper patients, with the addition, if the district board should see fit, of a sum in name of rent for the accommodation afforded. 4. This sum in name of rent should not exceed a charge calculated on the net cost of what may be required to provide the buildings, and we believe it would be an eventual saving to the ratepayers if the district board were empowered to charge the maintenance rate only in cases where they are satisfied that a higher rate cannot be afforded."

Edinburgh Royal Infirmary.

At a meeting of the managers of the Royal Infirmary held on Sept. 6th Dr. Argyll Robertson was appointed consulting ophthalmic surgeon, *his* term of office as acting surgeon *having expired.*

Sept. 7th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Proposed Isolation Hospital for Dublin.

A DEPUTATION, representing the guardians of the North and South Dublin Unions, waited on the corporation on the 6th inst. and appealed for a site for an isolation hospital at the Pigeon House Fort. After a long discussion the Right Hon. Alderman Meade explained that the Government had proposed to hand over to the corporation the whole of the plot of land at the Pigeon House by April 1st of this year, but had been unable to do so, the portion now in their possession being only a one-third instalment absolutely required for the purposes of the main drainage undertaking. The construction of the isolation hospital, though acknowledged on all hands to be desirable and, indeed, essential, is thus again postponed.

The Richmond Lunatic Asylum.

Arrangements to accommodate some of the healthy patients from the infected Richmond Lunatic Asylum are now being pushed forward. The *Dublin Gazette* of Sept. 3rd contained an order directing that the buildings and premises at Grangegorman, lately known as the Grangegorman Prison, should be made suitable and equipped for the Richmond District Lunatic Asylum at a cost not exceeding £2500.

Simpson's Hospital, Dublin.

The trustees of this old-established hospital will proceed, on Monday, the 13th inst., to elect a trustee in the place of the late Mr. Samuel Hunt Close.

Queen's College, Belfast: The President's Report.

From the interesting report of the President of Queen's College, Belfast, which has just been published, I find that during the past session, 1896-97, there were 380 students in attendance, of whom the large majority—227—were in the Faculty of Medicine, showing the great importance of the College as a medical school. Reference is made to the triennial visitation during the session at which the Senior Visitor—the Marquis of Dufferin—presided, and spoke in most laudatory terms of the work done at the College. During the past year Professor Everett, F.R.S., resigned, and Mr. W. B. Morton, M.A., was appointed in his place. He was an old Queen's College student, and was his predecessor's assistant. Two new departments were opened during last session—ophthalmology and otology—under the charge of Dr. McKeown, and a department of sanitary science under the joint care of Dr. Letts and Dr. H. Whitaker. The event of the year was the celebration of the jubilee of the foundation of the college, when the Lord-Lieutenant, Lord Lister, Lord Kelvin, and Lord Roberts were present, and a special feature of this function was the inauguration of the students' union. The advantages of this most desirable union to the students are very many indeed. At the time of the college jubilee the Lord-Lieutenant opened the new physiological and pathological laboratories, and a special address was delivered by Lord Lister. A fully equipped and endowed chair of pathology and bacteriology is much needed, and it is hoped the present President, who since his appointment in 1889 has done so much for the college, will be able, through his influence with rich Belfast merchants, to induce some of them to endow this chair. In the college library 832 volumes were added during the year, and a professors' reading-room has been arranged and opened, and a new catalogue has been issued. The President makes a strong appeal for a new physical and biological laboratory and for the completion of the chemical buildings, and for more funds for the support of the various scientific departments of the college. This report shows what good work the college is doing, and that if there are to be any changes in university matters in Ireland it has a strong claim to be made the centre of an Ulster or Northern university.

Health of Belfast.

From the report presented at the meeting of the city corporation on Sept. 1st I find that, as stated by the medical officer of health, Dr. Whitaker, "the health of the city is very unsatisfactory and its death-rate abnormally high." The number of deaths from typhoid fever and the number of cases of that disease are nearly double that of the previous month. The heavy death-rate—27·0 per 1000 (7·7 from zymotic diseases and 6·6 from chest affections)—is mainly due to deaths from diarrhœa, which, numbering 13 in the last

Digitized by Google

report, have during the past month amounted to 154. The infantile mortality was very high—276 as compared with 98 in the previous month. Dr. Whitaker says that he cannot tell the causes of this excessive number of deaths, nor does he know where they occurred except in a very vague way. He thinks that the main cause was diarrhœa, but he should, he says, be able to state this definitely, as also the streets or houses in which the deaths occurred. It is evident that the "Notification of Infectious Diseases Act" is not being thoroughly worked in Belfast. In the discussion on the matter at the corporation Dr. O'Neill (a councillor) having referred to the necessity of seeing that the cases were notified and that the houses were perfectly examined and put right, a lay member of the Public Health Committee made an extraordinary statement which will have to be considered by the medical societies. Referring to the large number of cases of typhoid fever reported he said that diseases were manufactured—that diseases were reported by some medical men in Belfast that never had any existence. He gave as evidence of this the fact that nine cases of cholera (evidently "English cholera") had occurred in Belfast. This was the way, he pointed out, that diseases, and among others typhoid fever, were reported in Belfast, and considering the action of some of the members of the profession he stated publicly that he regretted having been the means of introducing the Notification of Diseases Act into the city.

Newry Workhouse.

On Aug. 28th the Newry Board of Guardians re-elected as master of the workhouse the person whom the Local Government Board[1] had, as a result of an investigation held by their inspector, called on to resign as being unfit for the office. On Sept. 4th a letter was read at a meeting of the board of guardians of Newry from the Local Government Board transmitting a copy of an order under seal removing the newly-elected master from office and directing him to quit forthwith the workhouse premises.

The Belfast Hospital for Sick Children.

Owing to the resignation of Mr. Stack, Dr. J. S. Morrow has been promoted to the post of visiting surgeon, and Dr. Robert Campbell has been appointed assistant surgeon in his place.

Sept. 7th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Instantaneous Radiographs.

M. PORCHÉ recently brought before the Academy of Sciences a technical detail which is an important improvement in radiography as applied to practical medical use. It is well known how the length of time required for exposure makes the taking of a radiograph exceedingly difficult, especially when the subject is a little child whom it is utterly impossible to keep absolutely still. M. Porché proposes to get over this difficulty by the use of a fluorescent screen, and instead of taking a radiograph directly on the plate to photograph the shadow on the screen. An extremely sensitive plate is required, and this plate must be protected from all other rays emanating from the Crookes's tube except those which actuate the fluorescent screen. The method proposed by M. Porché is practical, but its results depend essentially on the rapidity of the sensitive plate.

Suicides in Hospitals.

A series of suicides has just occurred in the hospitals in spite of the excellent surveillance which exists in these institutions, so that, whether owing to the contagion of example so characteristic of suicides or the large number of hopeless cases which are found in hospitals, this new epidemic is somewhat disquieting. At the Maternity Hospital a young woman, aged twenty-eight years, threw herself from a window on the third storey at five o'clock in the morning and was instantly killed. She had previously threatened the nurse by throwing a tumbler at her head, and it was while the latter went to seek assistance that the patient committed the fatal act. At the Tenon Hospital a woman, aged fifty-five years, who had been under treatment for a long time, destroyed herself in the water-closet in a way which showed remarkable resolution. She set her nightdress on fire at the gaslight, and was so badly burned that she died on the following day. The other hospitals report cases of a similar kind.

The late Sir J. Tholozan.

You have recently announced the death of Sir J. Tholozan, National Associate of the Academy of Medicine, Commander of the Legion of Honour, and Physician to the Shah. Formerly assistant professor at the Val de Grâce, he was nominated by the French Government to fill the difficult and diplomatic post of physician to that monarch. Although loaded with presents by the Shah, whose confidence he always possessed, he frequently asked to be allowed to resign and to return to France, a request which was invariably refused. In 1889, during the visit of the Shah to France, Dr. Tholozan who had secretly conveyed all his property with him, made an attempt not to return to Persia, and another military medical man was nominated by the French Government to take up his office, for it was very important not to break through the tradition that France should be the country to furnish the sovereigns of Persia with their medical attendant who is so frequently a political adviser also. But the Shah could not console himself for the absence of Dr. Tholozan. He sent back his new physician at the end of two years, and most likely would have sought aid from some other foreign nation had not Dr. Tholozan from a strong sense of duty gone back at the age of seventy years to resume the post. He sent a variety of communications to the Academy of Medicine dealing with the pathology, the epidemiology, and the hygiene of Asiatic diseases, and also sundry papers on natural history.

Rabies in Paris.

Reported cases of rabies in animals, especially in cats, are becoming more and more numerous in Paris, and M. Lépine, the Prefect of Police, has just addressed a circular to the police commissaries reminding them of their duties in the matter. The prefect complains that dogs or cats suspected to be rabid which have bitten people are frequently knocked on the head and buried by private people or somebody in authority before any examination has been made to establish the fact whether they were or were not rabid. Moreover, these cases of bites are not reported to the administration or are only briefly mentioned. This method of procedure appears to M. Lépine to be contrary to the spirit of the law, and possibly a matter of great danger to public security. Accordingly the prefect begs the police commissaries to use the utmost care in reporting every case of bite. In cases where the animal was apparently rabid the report should be accompanied by a certificate signed by a qualified veterinary surgeon, stating the condition of the animal found upon two visits made at an interval of six days. In cases of undoubted rabies the report should be as complete as possible as regards the bitten, whether they be human beings or animals. In addition, the prefect recalls the fact that a special service presided over by a veterinary surgeon attached to the prefecture of police has been established in the pound in the Rue de Pontoise, where every day animals suspected of rabies or definitely affected by it are visited or their dead bodies examined. Both visits and examinations are absolutely gratuitous. The circular also requests the commissaries of police to ask the owner of every cat or dog suspected of being rabid—that is to say, one which has been bitten or even knocked over by a rabid animal—to have it killed at once, in conformity with Article 10 of the regulations of July 21st, 1881. With regard to persons bitten by an animal, either rabid or suspected to be so, they are begged to repair at once to the Pasteur Institute, where they will be treated. In conclusion, the prefect asks the commissaries of police of the suburbs to put themselves in communication with the municipal authorities of their district and to ask for their coöperation as to any case of rabies which may be brought to their knowledge, and also points out that in every commune where a case of rabies has been reported no dog may go out except in a leash for the following six weeks.

Prophylaxis in Contagious Diseases at School.

M. Courmont has published at the Congress of St. Etienne a report on the part played by the closing (*licenciement*) of schools in the prophylaxis of transmissible illnesses. According to him similar methods might be employed in families by the dispersion of their members or by their transport in block. There are advantages and disadvantages associated with *licenciement* which is of course difficult of execution,

[1] THE LANCET, Aug. 14th, 1897, p. 420.

Digitized by Google

and precautions must be taken in accordance with the rules of epidemiology before the method can be of sanitary service to the community.

Sept. 6th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The "Istituto Antirabico" of Milan.

LIKE "wisdom," the Pasteur Institute in Paris "is justified of all its children"—of none more than the Milanese "Istituto Antirabico," which works on the lines of the parent institute with a fidelity and care that have their reward in a yearly diminishing death-rate from one of the most terrible of maladies. The "cure" it practises is a "prophylactico-preventive cure," so that, in strictness of language, its practitioners do not speak of "patients" or "cures" in the case of persons who, bitten by mad dogs undergo the "cura antirabica," but rather of such as it has "immunised" beforehand against the eventual hydrophobic infection they may have contracted. Thus premised, it is well to recall the fact that before the adoption of the "cura antirabica" out of 100 persons bitten by mad dogs there was a mortality fluctuating between a minimum of 20 per cent. and a maximum of 60 per cent. In this death-rate the Pasteur method immediately wrought a signal diminution, causing it to sink to less than 1 per cent., a result obtained with not inferior success by the Milanese "Istituto," which, indeed, in this respect can boast a record scarcely equalled by the parent institute itself. The following statistics of the mortality in the Milanese "Istituto" suggest their own commentary:—

Years.	Per cent.
1889–91	1·00
1891–93	0·74
1893–95	0 54

In this connexion it may be well to add the figures of death from hydrophobia throughout Italy during the last decennium as these are given by the "Direzione Generale di Statistica" attached to the Agricultural Office under Government:—

Year.	Deaths from hydrophobia.
1886	136
1887	103
1888	106
1889	118
1890	75*
1891	97
1892	83
1893	83
1894	93
1895	53

* The asterisk indicates the year when the antirabic institutes were first opened in the Italian kingdom.

These figures, as I have said, speak for themselves and become even more eloquent when it is remembered that at least two-thirds of the above cited cases of death from hydrophobia are represented by individuals who had not been subjected to the treatment. But to return to the Milanese "Istituto." In the year now passing it had under treatment more than 250 persons bitten by undoubtedly mad dogs and it remanded without treatment some 150 more as not proper subjects for the same. Out of the former total there were 3 cases of hydrophobia, one of them not to be reckoned in the statistics because it terminated fatally twenty days after the bite and in the course of the "cura" itself, while the other two died without these qualifying circumstances. These two deaths out of the 250 cured and restored to perfect health constitute a result which, according to medical authority in the leading Milanese organ, the *Corriere della Sera*, is not only "satisfactory," but "such as to compare well with the results of past years classed as very good." The same journal quotes a distinguished compatriot physician as remarking: "It is not the case that persons under the hydrophobic access suffer those unutterable and unparalleled torments which many descriptive writers are prone to dwell upon. Death in these circumstances, indeed, cannot be called gentle or placid; but those who have witnessed it can attest that it is not more terrible or harrowing than death from tetanus, from various forms of heart disease, from pneumonia, or from typhoid fever. That which truly impresses and saddens the professional beholder is the impotence of the medical art to apply in such cases a treatment other than that of symptoms—its impotence to control a malady which inexorably runs its fatal course." All the more, then, must the putative victim to a hydrophobic bite lose no time in placing himself under the special treatment of the "Istituto Antirabico," whose demonstrated success cannot but supply another condition of "cure"—to wit, the confidence which antagonises the depression so invariably incident to the lesion.

The Water-supply of Milan.

This has long been a *vexata quæstio* in the Lombard capital, never more so than at present, when a formidable epidemic is filling its hospitals and scaring the travelling world from its hotels. At a meeting, on the 2nd inst., of its Consiglio Comunale the subject came up again, and in the course of discussion a number of facts leaked out which show how far the providing Milan with "acqua potabile," pure in quality and abundant in quantity, has yet to travel before being an accomplished fact. Several "consiglieri" were for postponing consideration of the question on the ground that the Junta, being about to resign, could not undertake pledges which would fall upon its successors. A majority contended that the matter was of such desperate urgency that it must be considered, if not put on a practical footing, then and there. Information was accordingly asked from the assessor and engineer, Signor Ponzio, as to the proposal to bring the desiderated supply from Garbagnate, and that gentleman, in a very lucid statement, referred to twenty-five different plans for providing Milan with "acqua potabile," and said that of these a technical commission appointed to consider the matter had cancelled seventeen. Of the remainder five were reserved for consideration, and that for transporting the water from Garbagnate was one of them. This, too, was in turn discarded by the commission, as it did not guarantee sufficient pressure to bring the water to Milan or to distribute it freely when brought; besides, the expenses required for the works were not adequately defined. Signor Ponzio concluded by maintaining that the Garbagnate plan must be relegated to the Greek Kalends, and added (what seems to be a fatal objection not only to it, but to all its rivals) that until the "fognatura" (drainage) was satisfactorily provided for the attempt to add to the volume and distribution of the "acqua potabile" would be tantamount to a blunder (*equivarrebbe ad un errore*). There was no answer forthcoming to Signor Ponzio's remarks, and the matter, though a vital one, remains *in statu quo*.

Experimental Hygiene in the Argentine Republic.

Improvement begets improvement nowhere more steadily than in science, and the "Istituto d'Igiene Sperimentale," founded by Professor Sanarelli in Montevideo, will soon have its counterpart in Buenos Ayres. With that object a Bill before the "Camera dei Deputati" of the last-named capital is rapidly proceeding through the several stages necessary to its becoming law. The management of the new laboratory, I hear, will be given to Professor Ferruccio Mercanti, the able sub-director of the "Istituto" over which Professor Sanarelli presides. Italians are congratulating themselves, and quite justifiably, on the progress their science is making in Southern America.

Sept. 5th.

CAMBRIDGE UNIVERSITY: EXAMINATION IN SANITARY SCIENCE.—The following is the order of examination for October, 1897. *Part* 1.—Tuesday, Oct. 5th: from 9 A.M. to 12 noon, Paper in Hygiene, in the Medical Schools, Downing-street, Cambridge; and from 2 to 6 P.M., Practical Bacteriology, in the Pathological Laboratory. Wednesday, Oct. 6th: from 9 A.M. to 12 noon, Paper in Hygiene, in the Medical Schools; and from 2 to 5 P.M., Practical Chemistry, in the Chemical Laboratory. Thursday, Oct. 7th: from 9 to 10.30 A.M., Paper in Bacteriology, in the Medical Schools; from 10.30 A.M. to 12 noon, Oral, in the Medical Schools; and from 2 to 6 P.M., Practical Microscopy and Oral, in the Physiological Laboratory. *Part* 2.—Tuesday, Oct. 12th: from 9 A.M. to 12 noon, Paper, in the Medical Schools; and from 1 30 P.M., Practical and Oral, in the Medical Schools. Wednesday, Oct. 13th: from 9 A.M. to 12 noon, Paper, in the Medical Schools; and from 1.30 to 5 P.M., Practical and Oral, in the Medical Schools. Thursday, Oct. 14th: at 10 A.M., Oral, in the Medical Schools.

Obituary.

JOHN BRAXTON HICKS, M.D., F.R.C.P. LOND., F.R.S.

JOHN BRAXTON HICKS was the second son of Mr. Edward Hicks, of Lymington, Hants, some time banker and for many years chairman of the bench of county magistrates, who was himself a native of Milford, Hants, which parish, together with the tything of Efford, originally belonged almost entirely to his immediate ancestors. The subject of this notice was born in 1823, and educated from the age of twelve to fifteen years as a private pupil of the Rev. J. O. Zillwood, of Compton Rectory, near Winchester. He then became an articled pupil of Dr. Fluder, of Lymington, until, on completing his eighteenth year, he entered as a medical student at Guy's Hospital, where he took first prizes in anatomy, materia medica, botany, and practical chemistry. Nor was Mr. Hicks unsuccessful in the world of athletics, for he obtained a medal for double sculling given by the then famous Guy's Hospital Boat Club.

In 1845 he passed with honours the first examination for the degree of Bachelor of Medicine at the University of London, obtaining an exhibition and gold medal for materia medica and a first (bracketed) in anatomy. In 1847 he passed the final M.B. with honours, and shortly afterwards became a Member of the Royal College of Surgeons of England and a Licentiate of the Apothecaries' Company. Four years later—in 1851—he obtained the M.D. at the University of London, and in the following year was elected a Fellow of the Linnæan Society. Ten years later Dr. Braxton Hicks was elected to the Fellowship of the Royal Society. He passed the examination for Membership of the Royal College of Physicians of London in 1859, and in 1866 was made a Fellow of the College. Dr. Hicks was appointed assistant obstetric physician to Guy's Hospital in 1858. Ten years later he became full obstetric physician and lecturer in obstetrics, and in ceasing his more active connexion with Guy's Hospital in 1883 he was made consulting obstetric physician. He was appointed examiner in obstetrics to the University of London and to the Royal College of Physicians of London from 1872–78, and again from 1889–93. In 1888 he accepted the invitation to the post of obstetric physician and lecturer at St. Mary's Hospital, and at the end of his term of service was appointed consulting obstetric physician to the same institution. For many years Dr. Braxton Hicks was physician to the Royal Maternity Charity, and afterwards consulting physician. For some years likewise he was physician to the Royal Infirmary, Waterloo-road. Dr. Braxton Hicks was President of the Obstetrical Society in 1871 and President and Orator of the Hunterian Society in 1879. He was also made an honorary Fellow of the Obstetrical Societies of Berlin, Edinburgh, and Philadelphia (U.S.A.), and of the American Gynæcological Society (U.S.A.). He was also corresponding Fellow of the Gynæcological Society of Boston (U.S.A.). To medical and scientific journalism Dr. Braxton Hicks has been a valued and voluminous contributor; he has also published many papers in Italian, American, and Australian medical journals. He was the original author of the "Combined External and Internal Version" (Longmans, 1864); also joint author of the "Earthworm and House Fly" (Van Voorst), engraving some of the illustrations with his own hand. From his boyhood upward he was a devoted student of natural science, and has published papers on original subjects in the Proceedings of the Royal Society. Among these may be noted "Eyes of the Invertebrata" and "Supplementary Forces concerned in the Circulation of the Uterus." In the Transactions of the Obstetrical Society he also published "Anatomy of Human Placenta." To the Transactions of the Linnæan Society he has contributed many papers on Zoology and Botany, and has described many groups of sensory organs on the surface of insects. In the same Transactions he also published papers on original researches on the "Lichens, Mosses, and Unicellular Algæ"; and papers on "Volvox Globator, Amœboid Vegetable Bodies," and "Gonidia of Lichens" have been contributed by him to the *Microscopical Journal*.

In the Medical Society's Transactions and the *American Journal* he has written papers on the "Effect of Movements of the Body on Respiration" and on "Abdominal Tension." Dr. Hicks was the inventor of some apparatus useful in nursing, in moving patients, also for making broths, &c. He was the founder of the Lymington Ambulance Centre for First Aid, and has given lectures to ambulance classes in the parish of St. George's, Hanover-square. He was also one of the post-graduate lecturers to medical men, and apart from his profession was for five years a vestryman in the parish of St. George, Hanover-square. A few months before his death he was elected Honorary Fellow of the Obstetrical Society.

Dr. Daniel Hooper writes to us as follows: "Braxton Hicks and I entered at Guy's Hospital in October, 1842, and were fellow students there till 1848; we sat on the same benches and fought for the same prizes and honours at the hospital and at the University of London. In those days Sir W. Gull coached the men who were preparing for the London degrees, and in his class were Hicks and myself, Wilks, Habershon, Cooper Forster, and others; now, alas, our coach and all his class, excepting Wilks and myself, have disappeared. Hicks and I were chums and worked together in our own rooms, in the dissecting-room, and in the chemical laboratory; we were both very fond of botany, and in the summer vacation used to exchange specimens of plants; his came from the New Forest, close to his home at Lymington, mine from the Sussex woods on my father's farm near Horsham. Hicks was a favourite pupil of Sir W. Gull and much liked by all who knew him. I shall never forget his amiable, cheerful expression, bright, piercing eyes, and noble forehead; his alacrity was remarkable; he was always busy—I never saw him idle for one moment—he would hurry with a very quick step to the lecture theatre, literally run down the steps (a huge volume of Pereira, perhaps, under his arm) to the bottom bench, and there sit motionless and attentive till the lecture was over. Of course, he carried off many prizes and honours at his school and university; and then, wishing to settle in practice and to marry, I introduced him to the late Mr. W. Moon, of Tottenham, whose assistant I was, and he bought a share of the practice. As a general practitioner he was popular and successful, but he was too good a man for Guy's Hospital to lose sight of, so he was invited to fill the post of assistant obstetric physician there. As is well known, he afterwards became full physician and finally consulting physician in his department. Hicks had an innate aptitude for scientific research, did much good work, and became a Fellow of the Royal Society. The profession has lost a distinguished member and I have lost one of my oldest and most esteemed friends."

ALFRED HALL, M.D. EDIN., F.R.C.P. LOND., &c.,
OF BRIGHTON.

DR. HALL, whose death we reported last week, was born in the year 1812, and so had reached the age of eighty-five years. He was the youngest son of Mr. John Cressy Hall, of Swanwick Grange, Alfreton, Derbyshire, barrister-at-law and Commissioner in Bankruptcy at Nottingham. He was the brother of the late Mr. Frederick Hall, J.P., barrister, of Furze Hill House, Brighton, a prominent and useful citizen. The honourable connexion of his family with the Bar is well continued in the person of his only surviving son, Mr. Marshall Hall, who with his sisters may be assured of the sympathy of a large number of members of the medical profession in the great loss they have sustained Dr. Hall had a large number of qualifications, the earliest obtained being the Licentiateship of the Society of Apothecaries, taken so far back as 1834, and the Membership of the Royal College of Surgeons of England, taken in 1835. He graduated at Edinburgh University in 1840, writing a thesis on Hydrophobia. In 1850 he obtained the Fellowship of the Faculty of Physicians and Surgeons in Glasgow in which city he practised both before and after his marriage. In 1859 he became a Member of the Royal College of Physicians of London, and in 1873 was elected to the Fellowship. The history of Dr. Hall's qualifications well represents his honourable ambition and his standing and work in the profession, "moving up from high to higher," acting the part of a general practitioner most admirably and to the great satisfaction of his patients, first, we believe, in Glasgow, then in Hounslow, where he was in partnership with the late Mr. Frogley about the years 1854–56, and finally in Brighton, where he held a very high position. Those who knew him best, either as a man or as a physician, will most easily understand how he came to be consulted by distinguished members of his own profession in Brighton. Among these was the late Dr. Marshall

Digitized by Google

Hall. Though there was no relationship between the families Dr. Alfred Hall's intimacy with Dr. Marshall Hall was that of men who deeply esteemed each other, and Mr. Marshall Hall bears the name, and is the godson, of the famous discoverer of the reflex functions of the spinal cord. Dr. Alfred Hall, too, as will be remembered by readers of THE LANCET, was the medical attendant of its Founder while he was at Brighton during his last illness, and was always much appreciated by him. Dr. Hall did much work in connexion with the medical charities of Brighton, especially the Brighton, Hove, and Preston Dispensary and the Brighton and Hove Hospital for Women. He also took an active interest in the movement for improving the drainage of Brighton.

Dr. Hall, owing to the illness of the late Mrs. Hall, left Brighton for Tunbridge Wells in 1887, but soon after her death he returned to Brighton, for which place he had a great liking. He was a good man and a model practitioner, kind, frank, cheerful, well up in the latest improvements in medicine, and always exercising his mind and good common sense in the treatment of individual cases. His handsome face and form well agreed with his nature, and are not likely soon to be forgotten by his friends.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men have been announced:—Dr. Eduard R. von Hoffmann, Professor of Forensic Medicine in the University of Vienna, on Aug. 27th. He was born in Prague in 1837, and studied there under Purkinje, Jaksch, Haller, Hasner, and Bochdalek. From the time he took his degree in 1861 until 1865 he worked as assistant in the Institute of Forensic Medicine connected with the Bohemian University of that city. He afterwards delivered the professorial lectures until 1869, when he was appointed professor at Innsbruck, where he remained until in 1875 he was appointed to succeed Professor Dlauhy in Vienna. He is chiefly known by his important Manual of Forensic Medicine, which was first published in 1878, and which has been translated into several languages.—Dr. Emerich Poór, Emeritus Professor of Dermatology in the University of Budapest, on Aug. 21st, in his seventy-fourth year. In early life he had been intended for the priesthood and was for some time in a seminary. When the war of Hungarian Freedom broke out he enlisted in the army and fought with his comrades until the battle of Ssény, when he was laid up sick in hospital. His military experiences seem to have changed his views as to entering the priesthood, and instead of returning to the seminary he entered the University of Pesth as a medical student, taking his degree in 1866. After this he studied for a time in Paris and Vienna, and on his return to Budapest was appointed to lecture for Professor Sauer, being subsequently given charge of the skin department of the Rochus Hospital and becoming an extraordinary professor of dermatology. As a medical journalist Dr. Poór takes a high rank, having founded and carried on, for many years alone, and afterwards with Dr. Dulécska as co-editor, the medical journal, *Gyógyászat*. He also deserves the thanks of his medical brethren for his activity in establishing a medical, social, and assurance association, called the *Orvosi kör*, of which he was president. For many years past he had been in bad health, and retired from his hospital work in 1890.

AN IMPROVED LIFEBOAT.—An officer in H.M. Customs residing at Bedminster, Bristol, has obtained a patent for a new lifeboat. He claims that it will live in any sea, is unsinkable, cannot be stove in or founder when put over the side of a vessel; that it can be mechanically propelled, and can be worked by either passengers or crew. There are two rudders, which will obviate the necessity of putting the boat about in a seaway and thus prevent the danger of capsizing.

SINGULAR DEATH AT GLOUCESTER.—An inquest was held in Gloucester on Sept. 2nd upon the body of a little boy aged six years. It appeared that the deceased went home on Aug. 31st and told his mother that he had been eating horse beans and was choking. The boy was sent to a medical man, but died before arriving there. A post-mortem examination showed that there were thirty-nine horse beans in the deceased's stomach and another one in his larynx. The jury returned a verdict of death from suffocation.

THE TWELFTH INTERNATIONAL MEDICAL CONGRESS.

MOSCOW, AUG. 19TH—26TH.

The Grand Duke Sergé's Garden Party.

THE last of the social functions in Moscow in connexion with the Congress was certainly one of the pleasantest. This was the garden party given by the Grand Duke Sergé Alexandrovitch on the afternoon of Friday, Aug. 15th (27th). The garden party was held in the grounds of the Neskoutchnaia Palace—a prettily situated Imperial villa, not far from the famous Sparrow Hills. The central part of the very extensive park consists of terraced lawns sloping down to the River Moskva and thickly dotted with flower beds. In an ordinary summer these gardens must be beautiful, but unfortunately the intense heat of the present summer had quite parched up every blade of grass, and it was pitiable to see what should have been bright green lawns converted into brown, desert-like expanses, with not one green blade of grass left. There appeared to be some 500 or 600 guests at the party, though the number of invitations issued was said to be considerably greater. There were many military bands scattered about the park, and the refreshments, served in two long marquees, were on a truly Royal scale. Shortly after four the Grand Duke Sergé and the Grand Duchess Elizabeth entered the gardens and remained for an hour and a half, talking freely with their guests, of whom large numbers were presented to their Imperial Highnesses.

The Exodus from Moscow.

All through the week the daily number of Congressists leaving Moscow was considerable, and no little strain was put upon the resources of the railway officials, more particularly on the lines to St. Petersburg and to Warsaw. On the Thursday and Friday evenings (and possibly also earlier in the week) special Congress trains were run on both these lines. Some little discomfort was inevitable under the circumstances. The free railway-ticket did not guarantee a sleeping-car, and on the return journey (which in this respect differed from the journey to Moscow) Congressists were unable to secure beforehand a sleeping-berth merely by paying the extra fee on their member's ticket. To obtain a sleeping berth it was necessary to pay the ordinary railway fare as well as the extra sleeping-car fee, and to go by one of the ordinary trains. Many members did this, and so secured a relatively comfortable night. Those who omitted to do so found the special Congress trains somewhat overcrowded.

The Entertainments in St. Petersburg.

Large numbers of Congressists proceeded to St. Petersburg after the close of the Congress in Moscow. Most excellent and hospitable arrangements had been made by the profession in St. Petersburg for their reception. Just as in Moscow, they were met by students at the station, who were ready to give them all information and to help in obtaining rooms or lodgings. A word, and much more than a word, of recognition and gratitude is due to both the students of St. Petersburg and Moscow for the way they have played their part during the past fortnight. They have in many instances gone to immense trouble to be of assistance to members, and have been invariably and under trying circumstances the embodiment of courtesy, kindness, and good temper.

On Saturday the proceedings in St. Petersburg consisted of a private reception by the Prince and Princess of Oldenburg at the Saxe-Altenberg Palace in the afternoon, and a "rout" at the *Duma*, or Town Hall, in the evening. The latter was attended by large numbers of guests. The decorations which had been put up on a lavish scale for the reception of M. Faure a few days before had been allowed to remain. The hall is a fine one at all times, but it looked particularly well thus decorated.

On Sunday invited members of the Congress were conveyed by four special steamer from St. Petersburg to Peterhof. The boats were timed to leave at 10.30 A.M., and Peterhof was reached about noon. The large palace, with its curiously decorated rooms, dating from the time

Digitized by Google

of Peter the Great, was thrown open, and at one o'clock a champagne lunch was served in the ball-room and dining-room. The afternoon, which unfortunately turned out wet, was occupied in walking about the park, and watching the wonderful series of fountains, all of which were playing. The fountains of Peterhof are said to surpass those of Versailles, and it seemed quite conceivable on Sunday that this bold statement was true. They are unquestionably a wonderful and beautiful sight. Many members drove round the park and town either in Royal carriages, of which a certain number were provided, or in hired vehicles. The little palace of Monplaisir, built by Peter, and containing many relics of that monarch, seemed to be a centre of attraction. Owing to the bad weather many members returned to town by train, but others braved the rain and remained until the special steamers started on their homeward journey at five o'clock.

On Monday morning a reception was held by the Prince and Princess of Oldenburg at the Imperial (formerly the Oldenburg) Institute of Experimental Medicine. This is certainly a most splendidly equipped institution, and more than one expert present declared his opinion that it must now take its place as the first institution of the kind in Europe, adding that Paris, Berlin, and Vienna cannot show anything to equal it. Whether this is so or not in sober fact an Englishman can only look at this institute in admiration and despair. After an inspection of all parts of the institute lunch was served in one of the larger rooms. In the evening the last social function of the Congress was held. This was a "farewell reception" given by members of the profession in St. Petersburg to members of the Congress. It was held in the *Dvoryanskoé Sobranyé*, or Salle de Noblesse, the largest concert-hall in St. Petersburg. A very excellent concert of Russian music was provided, followed by a series of performances by male and female choirs, and some interesting singing and dancing by a large choir of gipsies. Finally the guests themselves danced the Russian mazurka and some other dances, and an early hour in the morning was reached before the reception came to an end.

SECTION IV. (A).

GENERAL THERAPEUTICS, PHARMACOLOGY, BALNEOLOGY, CLIMATOLOGY, AND PHARMACY.

Dr. P. N. TACOWLEFF (Moscow) read an interesting note on the Treatment of Phthisis, in which he pointed out that even now at the present day there really do not exist any recognised specific methods of treatment, climatic or otherwise, for dealing with phthisical patients. Some forms of phthisis are curable in warm climates, and some improve under the temperature and environment of high mountain altitudes. But whatever the climate or hygienic conditions, two things are common to every environment that is to be of service to the phthisical patient, and they are: the air must be pure and the food good and nourishing; also the regular supervision of a physician is necessary. According to Dr. Tacowleff, climate does not play the important *rôle* in phthisis that has been attributed to it. Hygiene and a due attention to the *régime* of life are of more importance. To send the patient to high altitudes or to low altitudes or to southern resorts, where he obtains no surveillance from a medical man and where no care is taken to see that he is properly fed, is wrong. Far better that any case which requires prolonged treatment should receive that treatment in the country of the patient's birth. For example, with the Russians, Dr. Tacowleff preferred to order sojourn in the Russian plains to any journeying to Southern health resorts. Properly managed sanatoria and special hospitals in Russia could, he was certain, compete successfully with many well-known European localities, warm climate or high mountains not being indispensable conditions to the phthisical. In the case of the poor he considered that the special hospitals should be near the centres of industry, where phthisis is particularly rife, to be of the first use to the community. This opinion became common in Russia in 1892, when the late Emperor Alexander III. founded the first public sanatorium at Chalila in Finland. Last year a separate pavilion for phthisical patients was arranged in the Hospital of the Grand Duke Nicholas at Kief; and in December of the same year the Emperor Nicholas II. gave a large sum of money and a site for the foundation of a similar sanatorium near St. Petersburg. Now the municipality of Moscow proposes to found a popular sanatorium, and suggestions of the same character have been mooted in several other Russian towns. In Russia, particularly in the great towns, public sanatoria for the phthisical poor, however, ought to be replaced, in Dr. Tacowleff's opinion, rather by special hospitals for the sick, hospital discipline diminishing the risk of infection. Moreover, in special hospitals all the sick could be treated without distinction, while in the sanatoria only the curable sick would be treated, and, as a consequence, there must be greater difficulty in enforcing proper regulations as to isolation. Finally, Dr. Tacowleff came to the conclusion that in all the great towns of Russia it was now indispensable to build special hospitals for the gratuitous reception of the sick phthisical poor, and that the present sanatoria should be left for the better class who could pay, and who do not require the discipline of the hospital to prevent the risks of infection. From the hospitals the cases which are curable might be drafted into the sanatoria.

SECTION XIV.

HYGIENE.

Dr. A. M. KOROWINE (Moscow) read an interesting paper upon that familiar subject—the Drink Question. After premising that the question is one eminently for the consideration of medical men rather than of clergymen or lay philanthropists he came to the following conclusions among others: (1) That medical men should arrive at some idea when patients should be considered "moderate drinkers" and when "alcoholics"; (2) that they should study the influence and results of the exhibition of alcohol in disease in the cases of the abstainer and the non-abstainer; and (3) that they should make widely known the urgent need that exists that chronic alcoholic subjects should be treated as insane and be subject to confinement in asylums. Dr. Korowine's other conclusions were all directed towards obtaining for the disastrous effects of the alcoholic subject upon the community more direct notice from the medical profession. He wished his brother medical men to be more ready to recognise and point out to the public what are the ills, direct and indirect, that accrue to a nation through its drunkards, and to be more ready to lend their aid to any organisations at present working in the cause of temperance.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin*: Dr. T. W. Engelmann, Professor of Physiology in the University of Utrecht, has been appointed to the chair vacant by the death of Dr. du Bois Reymond.—*Copenhagen*: Dr. Leopold Meyer has been appointed Professor of Midwifery and Gynecology in succession to the late Dr. Stadfeldt.—*Heidelberg*: Dr. L. Brauer has been recognised as *privat-docent* of Internal Medicine.—*Kharkoff*: Dr. Ponomareff, Extraordinary Professor of Children's Diseases, has been appointed Ordinary Professor.

THE SALE OF COCAINE IN THE UNITED STATES.—It is announced that the State Legislature of Illinois has enacted the following law respecting the sale of cocaine: "Section I.—Be it enacted by the People of the State of Illinois, represented in the General Assembly, It shall not be lawful for any druggist or other person to retail or sell or give away any cocaine hydrochlorate or other salt of or any compound of cocaine or preparation containing cocaine, or any salts of or any compound thereof, excepting upon the written prescription of a licensed physician or licensed dentist, licensed under the laws of the State, which prescription shall only be filled once; Provided, that the provisions of this section shall not apply to sales in the usual quantities at wholesale by any manufacturer or wholesale dealer, when such manufacturer or wholesale dealer shall have affixed to the box, bottle, or package containing such cocaine hydrochlorate or other salt or compound of cocaine or preparation containing cocaine a label specifically setting forth the proportion of cocaine contained in any preparation. Section II.—Every person who shall be found guilty of violation of the provisions of this act shall, for the first offence, be fined a sum not less than $10 nor more than $50, and for each subsequent offence not less than $15 nor more than $200, or imprisonment in the county jail not exceeding thirty days, or either or both, in the discretion of the court."

HEAVY RAINFALL IN BRISTOL.—It is stated that with one or two exceptions the rainfall of August was the heaviest since 1860. During the month about 8 inches were registered in Bristol, and in the twenty-four hours ended Aug. 31st 2·49 inches fell. The average fall of rain for August for the fifty years 1841-1890 was 2·35 inches, and during August last year only 2·06 inches fell.

THE Sussex County Hospital has received £822 10*s.* 7*d.* out of the fund raised for the celebration of the Queen's Diamond Jubilee in Brighton, towards the cost of erecting the proposed Nurses' Home. This was the surplus left after paying for the various festivities in the town, and a cheque for the amount has been forwarded by the Mayor (Alderman Sir J. G. Blaker) to the hospital secretary (the Rev. W. H. Orton).

BEQUESTS TO ENGLISH HOSPITALS.—The secretary of the Princess Alice Hospital, Eastbourne, has received a communication to the effect that the late Baroness Solvyns left a considerable sum to be divided between the Société de Bienfaisance Belge, the London Fever Hospital, and the Princess Alice Memorial Hospital at Eastbourne, in memory of the late Baron Henry Solvyns, formerly Belgian Minister in London. The executor is prepared to pay £400 at once to the Eastbourne Hospital, and a further sum is about to be obtained from the sale of a house in New York.

THE honorary secretaries of the Prince of Wales's Hospital Fund have received from Mr. W. Y. Campbell, of Johannesburg, South African Republic, the generous contribution of £1602 5*s.* 3*d.*, made up of sums contributed by the following bodies:—The Queen's Record Reign Witwatersrand Celebration (W. Y. Campbell, treasurer)—British residents of Witwatersrand, Transvaal, £1452 5*s.* 3*d.*; Britons of Potchefstroom (per Mr. Mountfield), £120; the Nigel Gold Mining Company, Limited (A. Grant, general manager) and employés, £30; total, £1602 5*s.* 3*d.*

FORMIC ALDEHYDE AS A DISINFECTANT.—Some interesting experiments on the production of formic aldehyde and its efficacy as a disinfectant have been published by Dr. F. C. Robinson, who investigated the subject at the instance of the Maine State Board of Health. He at first used an ordinary lamp with thin platinum, or platinised asbestos, above or surrounding the wick. He found the asbestos better than sheet platinum, but the amount of gas obtained was insufficient, and he subsequently devised the following arrangement, which seemed to him to be very satisfactory. A disc of moderately thick asbestos board was perforated with small holes close together, and then platinised in the usual way, using quite a strong solution of platinic chloride. If now a shallow dish, cylindrically formed, and of such a size that the perforated asbestos disc will just cover its top, be partly filled with methyl alcohol, it serves as the lamp font. If the platinised disc be wetted with the alcohol, seized in a pair of forceps or small tongs, removed from the dish, and the alcohol lighted, it will, by the time its alcohol burns away, be heated sufficiently, so that when placed over the lamp-font again it will continue hot and change the alcohol to formaldehyde. Experience shows that with proper depth of dish and suitable holes for the admission of air the disc keeps of a proper redness to bring about the change most efficiently. In order to avoid all chance of the alcohol catching fire, and to provide for regulation of the air-supply, Dr. Robinson constructed an apparatus the advantage of which is that it is easily used and the amount of alcohol changed in a given time depends upon the size of the disc. A disc about six inches in diameter serves to change a litre per hour, and this is about as much as is ever wanted. This form of apparatus also seems to give a larger yield of aldehyde than any other. It exposes a much larger surface of platinum to the alcohol and air than any other, and keeps it at a more uniform temperature. Having constructed a lamp in the manner described Dr. Robinson next undertook a series of experiments, which in general tended to confirm the results of others. In a room containing about 3000 cubic feet, and having three large windows with very loose sashes, he found that, one litre of alcohol being used and the room being closed for four hours, infected matter was not completely sterilised if it was covered up or concealed to any great extent, but when two litres were used, or even one and a half, complete sterilisation resulted in about three and a half hours. Diphtheria and typhoid cultures were rendered completely sterile, so that there was no turbidity in any of the cultures within two days.

MEDICAL MAGISTRATE.—Mr. Roger R. S. Mackinnon, M.B., Ch.M. Syd., of Warialda, New South Wales, has been appointed a magistrate for the colony.

AT the annual meeting of the School of Mines Bendigo, Australia, Mr. O. Penfold, M.R.C.S. Eng., L.S.A. Lond., Honorary Medical Officer to the Bendigo Hospital, was elected President.

NEGRO MEDICAL PRACTITIONERS.—The Chicago *Railway Surgeon* mentions as an exceptional occurrence that a negro woman, Emma Wakefield, of Louisiana, has graduated in the medical department of the New Orleans Coloured University and lately was licensed to practise by the Louisiana Board of Examiners. According to the *North Carolina Medical Journal* a negress was licensed in North Carolina in 1894. The *Maryland Medical Journal* states that a congress of coloured physicians met in Washington last July to perfect arrangements for a national association of the physicians of that race.

THE SANITARY INSTITUTE.—The sixteenth congress of the Sanitary Institute will be held at Leeds from Sept. 14th to Sept. 18th. A reception room will be opened at the town hall on Sept. 13th, at 12 noon, and on the following days at 9 A.M. for the issue of all tickets in connexion with the Congress. On Sept. 14th the reception of the members will take place in the town hall at 12 30 P.M.; there will be a public luncheon in the large hall, Yorkshire College, at 1.30 P.M.; and the inaugural address by the President (Dr. Robert Farquharson, M.P.) will be delivered in the Yorkshire College at 3 P.M. On Sept. 15th the following conferences will meet: River Pollution (President, Major L. Flower); Municipal Representatives (President, Councillor B. Womersley); Medical Officers of Health (President, Dr. Edward Seaton); Municipal and County Engineers (President, Mr. Thomas Hewton); Sanitary Inspectors (President, Mr. Peter Fyfe, Glasgow); and Domestic Hygiene (President, Mrs. Fawkes). The sectional meetings on the following subjects will be held in the town hall on Sept. 16th and 17th: Section I., Sanitary Science and Preventive Medicine (President, Mr. T. Pridgin Teale); Section II., Engineering and Architecture (President, Mr. Lewis Angell); and Section III., Chemistry, Meteorology, and Geology (President, Mr. William Whitaker). The closing general meeting will be held in the town hall on Sept. 17th, at 5 P.M. Saturday, Sept. 18th, will be devoted to excursions. The health exhibition in connexion with the Congress will be open from Sept. 14th to Oct. 9th.

PRESENTATIONS TO MEDICAL MEN.—Mr. Hugh Kirkland, M.B., Ch.M. Glasg., of Bathurst, New South Wales, was entertained at a smoking concert on June 2nd and afterwards made the recipient of an illuminated address.—Mr. Charles N. Simons, L.R.C.S. Irel., lately of Brighton, Victoria, Australia, has been presented by the residents, on the occasion of his leaving the district, with a purse of sovereigns and an illuminated address. The mayor, on making the presentation, referred to the sanitary improvements in the town effected by Mr. Simons in his capacity as health officer.—Mr. John Wood, M.B. Oxon., L.R.C.S. Edin., of Walsall, Staffordshire, on his removing from that town received the gift of an ebony and gold clock, and a richly illuminated address. The clock bears the following inscription: "Presented to John Wood, Esq., M.A., M.B., on his resigning his position as senior physician to the Walsall and District Hospital, by members of the Committee and a few other friends. August, 1897." Dr. Wood was connected with the hospital for the long period of twenty years, and has rendered valuable and appreciated services to the institution as surgeon and physician.—At the recent annual meeting of the Bentinck Colliery Ambulance Class, held in the Kirby Board School, Mr. John Mackenzie, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., was the recipient of a timepiece, barometer, and thermometer as tokens of acknowledgement for his lectures on First Aid. The class, which is a large and successful one, was held for the first time last year in connexion with the new Bentinck Colliery, and will be resumed during the coming winter.—On the occasion of his leaving Llandilo through continued ill-health, after practising there for eleven years, Mr. Rees Morgan, L.R.C.P. Edin., L.F.P.S. Glasg., has been presented by his patients and friends at Llandilo and district with an artistically printed

Digitized by Google

address and an oil painting of himself. At the same time Mrs. Morgan was the recipient of a tea service.

BILLINGSGATE AND THE HOSPITALS.—The *City Press* says: "In 1892 Mr. Sol Parker, of Billingsgate Market, founded a fund in connexion with the market for assisting the various hospitals of the metropolis, and the fund is not only still in existence, but is in a flourishing position. The patrons include the alderman of the ward (Sir Reginald Hanson, Bart., M.P.) and Mr. Deputy Sayer. Last year the amount collected was nearly £150, while there were 540 letters distributed. It is proposed this year to make a further step in advance, and to hold some athletic sports in aid of the fund. These will take place on Monday, the 13th inst., at the Memorial Recreation Grounds, Canning Town. The City Band will be in attendance. Miss Gertrude Sayer has kindly consented to distribute the prizes."

THE DAVID LEWIS TRUST.—The two public recreation grounds given by the Lewis trustees, one for Manchester, at Blackley, adjoining Boggart Ho' Clough, and the other for Salford, on the Broughton side of Peel Park, have recently been opened with some ceremony. The Blackley ground, of about nineteen acres, was bought for £8000, and £9000 have been spent in laying it out. A bowling-green, gymnasium, tennis courts, and bandstand have been provided, but the greater portion has been set aside as a playground for children, mainly for cricket and football. The Salford ground is still larger. It was purchased for £10,000 and laid out at a cost of £5500, and the trustees have promised a further sum of £245 for trees and shrubs. Certain parts of the grounds are to be set aside "for the sports of children of both sexes under fourteen years of age." The deed also prohibits "the holding of meetings, demonstrations, gatherings, or services." The somewhat elaborate scheme of the trustees for the amalgamation of St. Mary's Hospital and the Southern Hospital was burdened with conditions that the managers, of St. Mary's Hospital especially, considered too arduous, and it broke down. At the luncheon at the town hall Sir William Houldsworth, M.P., one of the trustees, gave utterance to a significant remark. Speaking of the difficulty of spending money wisely he said: "At one time they had thought of assisting the hospitals of the city in some way or other, and especially the hospitals for women and children. It was generally supposed that no difficulty would be experienced in giving funds to a hospital, but they at any rate had found one." He went on to say that it might turn out a blessing, for "they seemed now to be going on the lines of trying to prevent disease." Presumably therefore the hospitals must not hope for help from the trust, and the danger is once more shown of looking a gift horse in the mouth. It is certain, however, that these gifts are as wise as they are munificent.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

BABINGTON, S. N., L.R.C.P., M.R.C.S., has been appointed House Surgeon to St. Thomas's Hospital.

BATTEN, WM. S., M.R.C.S., L.S.A., has been re-appointed Medical Officer for the Second Sanitary District of the Calne Union.

BOWRING, G. B., B.A. Cantab., has been appointed a Clinical Assistant at the Convalescent Home, Cheadle.

COBB, E. H., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Skin at St. Thomas's Hospital.

COOPER, H. G., L.R.C.P., M.R.C.S., has been appointed a House Physician to the Manchester Royal Infirmary.

CURLING-HAYWARD, W., M.R.C.S., L.R.C.P., has been appointed House Physician to Charing-cross Hospital.

FACEY, S. H., M.R.C.S., L.R.C.P. Lond., has been appointed Resident Clinical Assistant, vice W. S. Nicholl, resigned.

FAIRBAIRN, J. S., B.A., M.B., B.Ch. Oxon., L.R.C.P., M.R.C.S., has been appointed Senior Obstetric House Physician to St. Thomas's Hospital.

FRAZER, W. D., L.R.C.P., M.R.C.S., has been re-appointed Clinical Assistant in the Special Department for Diseases of the Ear at St. Thomas's Hospital.

GILBERT, L., L.R.C.P., M.R.C.S., has been appointed House Surgeon to St. Thomas's Hospital.

GOODE, H. N., L.R.C.P., M.R.C.S., has been appointed House Physician to St. Thomas's Hospital.

GREEN, REGINALD, M.D., B.Hy., has been re-appointed Medical Officer of Health and Medical Superintendent to the Fever Hospital for the County Borough of Gateshead.

HALL, J. S., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

HARTLEY, H., M.B., Ch.B. Vict., has been appointed a House Surgeon to the Manchester Royal Infirmary.

HINDLEY, G. D., B.A. Oxon., L.R.C.P., M.R.C.S. has been appointed Junior Obstetric House Physician to St. Thomas's Hospital.

HOPKINSON, E., B.A. Oxon., L.R.C.P., M.R.C.S., has been appointed Senior Ophthalmic House Surgeon to St. Thomas's Hospital.

HUNTER, A., M.B., C.M. Aberd., has been appointed Medical Officer of the Aberdeen Dispensary, vice J. A. R. Glennie, resigned.

JONAS, H. C., L.R.C.P., M.R.C.S., has been re-appointed House Physician to St. Thomas's Hospital.

LLOYD, D., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer of Health by the Newcastle Emlyn Rural District Council.

MCCLEAN, J. F., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

MCDOUGALL, ALAN, M.B., B.Ch. Vict., M.R.C.S., has been appointed Resident Medical Officer at the Manchester Royal Infirmary.

MCDOUGALL, W., M.A., M.B., B.C. Camb., has been appointed House Physician to St. Thomas's Hospital.

MARMION, E. J., M.B. Durh., L.F.P.S. Glasg., has been appointed Medical Officer of Health by the Milton Urban District Council.

MARRIAGE, H. J., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

MORGAN, THOS., L.R.C.P., L.R.C.S. Irel., has been appointed Medical Officer of Health for the Borough of Montgomery.

MORGAN, W. H., M.R.C.S., L.R.C.P., has been appointed House Surgeon to Charing-cross Hospital.

MUIR, J. O., M.B. Cantab., L.R.C.P., M.R.C.S., has been appointed a House Surgeon to the Manchester Royal Infirmary.

MYERS, W., M.A., M.B., B.C. Camb., B.Sc. Lond., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Throat at St. Thomas's Hospital.

OSBORN, E. C., L.R.C.P. Lond., has been appointed First Assistant Medical Officer at the Infirmary, Parish of Kensington.

PATERSON, W. H. J., L.R.C.P., M.R.C.S., has been appointed House Surgeon to St. Thomas's Hospital.

PATTERSON, J. H., M.B., C.M. Edin., has been appointed House Surgeon to the Huntingdon County Hospital.

PENFOLD, OLIVER, M.R.C.S., L.S.A., has been appointed Honorary Surgeon to the Bendigo Gold District General Hospital, Bendigo, Victoria, Australia.

REED, J., M.R.C.S., L.S.A., has been appointed a Public Vaccinator for the Ashurst District, New Zealand.

ROUILLARD, J. A. A., L.R.C.P., M.R.C.S., has been re-appointed Clinical Assistant in the Special Department for Diseases of the Throat at St. Thomas's Hospital.

SANGUINETTI, H. H., B.A., M.B., B.Ch. Oxon., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

SCOTT, H. HAROLD, M.R.C.S., L.R.C.P. Lond., has been appointed Resident House Surgeon to the Teignmouth Hospital, South Devon.

SELIGMANN, C. G., L.R.C.P., M.R.C.S., has been re-appointed House Physician to St. Thomas's Hospital.

SMITH, ROBT., F.R.C.S. Edin., L.R.C.P., L.R.C.S. Edin., has been appointed Health and Medical Officer to the Police, Gaols, and Paupers, Tasman and Forestier Peninsulas.

STAINER, E., M.A., M.B., B.Ch. Oxon., has been appointed Clinical Assistant in the Special Department for Diseases of the Skin at St. Thomas's Hospital.

STANFORD, W. B., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Workhouse and Infirmary of the parish of St. Mary, Islington, vice C. S. J. Wright, resigned.

STOKER, H., L.K.Q.C.P. Irel., L.R.C.S. Irel., has been appointed Health Officer and Superintendent of the Quarantine Station, Point Nepean, Victoria, Australia, vice S. H. Browning.

SWEET, G. B., M.B., Ch.M. Syd., has been appointed a Public Vaccinator at Whangarei, New Zealand.

TUKE, A. W., L.R.C.P., M.R.C.S., has been appointed House Surgeon to St. Thomas's Hospital.

TURNER, S. D., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Ear at St. Thomas's Hospital.

TYRRELL, F. A. C., B.A., M.B., B.C. Camb., L.R.C.P., M.R.C.S., has been appointed Junior Ophthalmic House Surgeon to St. Thomas's Hospital.

WOOLLEY, G. T., M.R.C.S., has been appointed Health Officer for Castlemaine, Victoria, Australia, vice Dr. Reid.

WOOLLISCROFT, W. W., M.R.C.S., L.R.C.P., has been appointed House Surgeon to Charing-cross Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BATH ROYAL UNITED HOSPITAL.—House Surgeon, for one year. Salary £60, with board, lodging, and washing.

BIRMINGHAM AND MIDLAND EYE HOSPITAL, Birmingham.—Assistant House Surgeon. Salary £50 per annum, with apartments and board.

BRISTOL ROYAL INFIRMARY.—Resident Casualty Officer for six months. Board, lodging, and washing provided. Conditional honorarium of £10.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Clinical Assistant.

GENERAL HOSPITAL, Birmingham.—Anæsthetist, for one year. Salary £40.

GUEST HOSPITAL, Dudley.—Resident Assistant House Surgeon for six month. Board, lodging, and washing in the hospital provided.

HOSPITAL FOR WOMEN, Soho-square, London.—Assistant House Physician, non-resident, for three months.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—House Physician, House Surgeon, Assistant House Physician, and Assistant House Surgeon. All for six months. Salary of House Physician and House Surgeon each at the rate of £40 a year, and of the Assistant House Physician and Assistant House Surgeon each at the rate of £20 a year.

Digitized by Google

ROYAL CORNWALL INFIRMARY, Truro.—House Surgeon, unmarried. Salary, first year, £120, increasing by £10 a year to £150, with furnished apartments, fire, lights, and attendance.

SALOP INFIRMARY, Shrewsbury.—House Surgeon. Salary £100 per annum, with board and residence.

SOUTHPORT INFIRMARY.—Senior House Surgeon. £80, tenable for two years. Junior House and Visiting Surgeon. £30, tenable six months, and renewable. All found.

STAFFORDSHIRE GENERAL INFIRMARY, Stafford.—Assistant House Surgeon. Salary £30 per annum, with board, lodging, and washing.

WEST HAM HOSPITAL, Stratford, E.—Junior House Surgeon for one year. Salary £35 per annum, with board, residence, &c.

Births, Marriages, and Deaths.

BIRTHS.

BLAKE.—On Sept. 6th, at Elsinore, Ventnor, Isle of Wight, the wife of Victor John Blake, M.B., B.S. Lond., M.R.C.S. Eng., &c., of a daughter.

BUCHANAN.—On Sept. 4th, at Hammersmith-terrace, W., the wife of G. S. Buchanan, M.D., of a son.

HAWES.—On Sept. 3rd, at Pangbourne, the wife of G. Charles B. Hawes, M.R.C.S., L.R.C.P. Lond., of a son.

RENDALL.—On Aug. 21st, at Aix-les-Bains, France, the wife of Stanley Rendall, M.D., of a daughter.

WREFORD.—On Sept. 1st, at Mount Edgcumbe-gardens, Clapham-road, the wife of S. Wreford, M.R.C.S., of a son.

MARRIAGES.

HADLEY—CHARRINGTON.—On Sept. 1st, at Holmbury St. Mary, near Dorking, Wilfred J. Hadley, M.D., of Harley-street, Cavendish-square, W., to Joanna Margaret, widow of the late Ernest Charrington, of Parkside, Reigate.

HILDIGE—LIDDELL.—On Sept. 4th, at St. Michael's Church, Burleigh-street, Strand, London, Henry Johnson Hildige, L.R.C.P., and L.R.C.S.I., of Brookfield, Pinner, to Mary Evelyn, youngest daughter of William Liddell, J.P., Banogue House, Donacloney, Lurgan, Ireland.

HOUGHTON—LARKIN.—On Sept. 1st, at the Church of the Sacred Heart, Quex-road, Kilburn, Murtaugh James Houghton, M.R.C.S., L.R.C.P., son of the late Matthew Parsons Houghton, of Radford House, Coventry, to Kathleen, daughter of Hugh Larkin, of Kenilworth-road, Brondesbury.

KEELE—ATKINS.—On Sept. 2nd, at the Parish Church, Rocester, David Keele, M.R.C.S., L.R.C.P., son of George Thomas Keele, M.R.C.S., of Highbury, to Jessie Augusta, second daughter of William Atkins, of Rocester, Staffordshire.

MANNING—COLES.—On Sept. 1st, at the Priory Church, Malvern, Thomas Davys Manning, M.B., B.S., of Hoddesdon, Herts, to May, only daughter of the late Colonel C. H. Coles, Bombay Staff Corps (9th Bo. I.).

RUBEL—WYNNIATT.—On Sept. 7th, at the Church of St. Peter and St. Paul, Temple Ewell, near Dover, by the Rev. John Turnbull, M.A., Vicar, assisted by the Rev. S. M. Statham, M.A., John Leopold Rubel, M.R.C.S. and L.R.C.P., only son of J. Rubel, Esq., Wood-lane, Shepherd's-bush, to Maude, elder daughter of the late James John Wynniatt, late 52nd Light Infantry and 10th Royal Hussars.

SKERRETT—KERRY.—On Aug. 31st, at St. Giles's, Camberwell, Frederick Thomas Skerrett, Surgeon-Captain, Army Medical Staff, to Rose Edith, elder daughter of the Rev. F. F. Kelly, LL.M., Vicar of Camberwell.

WATKIN-DAVIES—METHVEN-ROBERTS.—On Sept. 4th, at All Saints', Margaret-street, E. O. Watkin-Davies, B.A., M.B., T.C.D., younger son of the late Rev. D. Watkin-Davies, M.A., Rector of Llanrhyddlad, Anglesey, to Frances Methven, widow of the late R. Methven-Roberts, of Plas yn Green, Denbighshire.

YOUNG—STRANG.—On Sept. 1st, at All Saints Church, Blackheath, by the Rev. Hamilton S. Cobb, M.A., of St. Mark's, Lewisham, assisted by the Rev. W. L. Groves, M.A., Hugh Corbett Taylor Young, M.D., C.M., of Sydney, N.S.W., to Annie Rankin, only surviving daughter of William Strang, of Blackheath, S.E. Australian and New Zealand papers please copy.

DEATHS.

COLLEY.—On Sept. 1st, at Ladismith, Cape Colony, South Africa, Courtenay Rossiter Colley, M.R.C.S., L.R.C.P. Lond., elder son of the late Charles C. Colley, of Carisbrooke, Mount Nod-road, Streatham, aged 27 years.

DALE.—On Sept. 2nd., suddenly, at Nightingale-park-crescent, Wandsworth-common, George Cornelius Dale, M.D., aged 75 years.

FORRESTER.—On July 22nd, at Wycheproof, Victoria, Australia, after a few days' illness, of pneumonia, Robert Alexander Paul Forrester, B.A., Trinity College, Dublin, and M.B., C.M. Edinburgh University, only son of Paul Robert Forrester, late English master, Kilmarnock Academy, and Fellow of the E.I.S. Friends will please accept this intimation.

TURNBULL.—On Sept. 6th, at Tunbridge Wells, James Muter Turnbull, M.D., F.R.C.P., late of Liverpool, Consulting Physician to the Royal Infirmary, aged 79 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1897, which was completed with the issue of June 26th, was given in THE LANCET of July 3rd. It is intended, in future, to include the Index and Title-page for each past half-yearly volume in the first number of the succeeding volume, as in the present case, instead of in the last number of the volume itself, as heretofore.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1897 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

THE ISOLATION OF ARMY MEDICAL OFFICERS.

"AN OLD SOLDIER" writes to us on the causes of the alleged isolation of army doctors, which he attributes mainly to two causes—namely, their separation from corps and regiments, and their having been constituted into a separate body for one thing, and their desired assumption of purely military titles for another. The writer of this communication expresses himself with no unkindly feeling to medical officers—quite the reverse; but we do not see that any good would arise from the publication of his letter, which does not accurately state the case. It was not in the interest of the medical officers that their regimental connexion was severed, but in the interest of the State and for the efficiency of military service, and the occasion for the present feeling first arose out of the abolition of relative rank.

A MODIFIED FORM OF BOTTINI'S PROSTATIC CAUTERY.

BOTTINI'S prostatic cautery has an external tube resembling a catheter with a longitudinal opening on the concave aspect of its bend, this opening being made for the reception of a platinum galvano cautery which is capable of being moved along the stem for a short distance. The wires within the tube convey the galvanic current to the cautery, the remainder of the instrument being kept cool when it is in use by means of a stream of water circulating through it. Dr. Albert Freudenberg, of Berlin, after having repeatedly operated with the instrument in its original form, was led to make some modifications in the details of its construction, whereby it seems to be improved without any departure from the general principles followed by the original inventor. The new instrument has a stout cylindrical handle, through which the cooling water circulates, as well as through the stem. The cautery is not made of platinum, but of platinum-iridium, which is harder than the former and requires less current to heat it, as it has a higher electrical resistance; the two conducting wires are replaced by a much stouter wire which is attached to one end of the cautery, the other end of the cautery being riveted to the rigid tube; finally, the new instrument is three inches shorter than the original one, and its connexions with the wires supplying the current are much less likely to be in the way of the operator. The most important advantage, however, which Dr. Freudenberg claims for his instrument is that it is not injured by antiseptic solutions and may be effectually sterilised by boiling. The cautery not being in sight during an operation, there was in the original instrument no means of ascertaining its temperature, and its power of penetrating the tissues could only be estimated from the sensation of resistance communicated to the hand while its position was being gradually altered. To remedy this defect Dr. Freudenberg has added an electrical accumulator provided with an ampère-meter, which enables the operator to read the strength of the current at any time, and thereby gives him an indication of the temperature of the cautery. This accumulator will, of course, serve for most kinds of galvano-cauteries as well as for Bottini's cautery.

Dr. William Roberts.—The degrees mentioned are not registrable in England, and would not, therefore, legalise medical practice here by gentlemen holding them. Our correspondent is advised to write to the Registrar of the General Medical Council, 299, Oxford-street, London, W., for further information.

C. P. (Dalston).—We never recommend individual practitioners. Our correspondent must obtain the information from his own medical man.

"AN URGENT APPEAL."

To the Editors of THE LANCET.

SIRS,—I desire to gratefully acknowledge the enclosed subscriptions on behalf of the widow and eight children of the late Mr. Campe. Again would I earnestly commend this saddest of cases to the generous sympathy of the medical profession.

I am, Sirs, yours faithfully,

36, New-road, Rotherhithe, Sept. 8th, 1897. WM. ASTLEY COOPER.

	£	s.	d.		£	s.	d.
Mr. Terry (Bath)	5	0	0	Mr. C. T. B. Maisey... ...	1	1	0
J. E. J. (an old Guy's man)	0	10	0	Mr. J. Faraker	0	10	6
Dr. Wm. Easby	0	5	0	G. W. D.	0	5	0
Dr. Domett Stone	1	1	0	Mr. Wm. Astley Cooper...		1	0

Mr. A. H. Nicholson.—Application should be made to the Secretary of the Royal Medical Benevolent College, Mr. J. B. Lamb, 37, Soho-square, W.

Mr. William Moor.—We should advise our correspondent to try yet another "orthodox aurist."

A CURIOUS BICYCLE ACCIDENT.

ONE of our cial correspondents at Montreal writes: "At the annual meeting of the Montreal Bicycle Club, held here on Aug. 28th, a remarkable cycling accident happened. It occurred in the first heat of the two-mile tandem race, when, during a spurt in the last lap at the far curve on the south side of the grounds, where the track curves up against the fence surrounding the grounds, the tandem ridden by L. S. Robertson and J. Drury became unmanageable. The machine actually jumped the fence, which is over three feet high, and the pedals of the one ridden by Provencher and Eaves becoming entangled with it their machine followed it. The four men and the two machines disappeared over the fence as if the earth had swallowed them up. Beyond a few bruises to the men and a broken chain on one of the machines no damage was done. Provencher and Eaves were able to ride in the final heat, but Robertson had to go home in a cab. It was a remarkable incident and a wonder that any of the riders escaped without broken bones."

THE CONVEYANCE OF DEAD BODIES ON AMERICAN RAILWAYS.

IN a paper read not long ago on the Relation of Railway Companies to State Boards of Health Dr. G. P. Conn, chief surgeon to the Boston and Maine Railway, stated that a few years ago the National Association of Baggage Agents formulated the following rules, which have been adopted by railroads and State boards of health throughout Pan-America:—

"Rule 1.—The transportation of bodies of persons dead of small-pox, Asiatic cholera, typhus fever, or yellow fever is absolutely forbidden.

"Rule 2.—The bodies of those who have died of diphtheria, anthrax, scarlet fever, puerperal fever, typhoid fever, erysipelas, measles, and other contagious, infectious, or communicable diseases, must be wrapped in a sheet thoroughly saturated with a solution of bichloride of mercury in the proportion of one ounce of the bichloride to a gallon of water, and encased in an air-tight zinc, tin, copper, or lead-lined coffin, or in an air-tight iron casket, hermetically sealed and all enclosed in a strong, tight, wooden box; or the body must be prepared for shipment by being wrapped in a sheet and disinfected by a solution of bichloride of mercury as above, and placed in a strong casket or coffin, and said casket or coffin encased in a hermetically sealed (soldered) zinc, copper, or tin case, and all enclosed in a strong outside wooden box, of material not less than one and one-half inches thick.

"Rule 3.—In cases of a contagious, infectious, or communicable disease the body must not be accompanied by any articles which have been exposed to the infection of the disease. And in addition to a permit from the board of health or proper health authorities station agents will require an affidavit from the shipping undertaker stating how the body has been prepared and the kind of coffin or casket used, which must be in conformity with Rule 2.

"Rule 4.—The bodies of persons dead of diseases that are not contagious, infectious, or communicable may be received for transportation to local points in the same state, when encased in a strong coffin or metallic case and enclosed in a strong wooden box securely fastened so that it may be safely handled. But when it is proposed to transport them out of the state to an interstate point (unless the time required for transportation from the initial point of destination does not exceed eighteen hours), they must be encased in air-tight zinc, tin, copper, or lead-lined coffin, or an air-tight iron casket, or a strong coffin or casket encased in a hermetically sealed (soldered) zinc or tin case, and all enclosed in a strong outside wooden box of material not less than one inch thick. In all cases the box must be provided with four iron chest handles.

"Rule 5.—Every dead body must be accompanied by a person in charge, who must be provided with a ticket marked 'Corpse,' and a transit permit from the Board of Health or proper health authority, giving permission for removal, and showing name of deceased, age, place of death, cause of death (and if a contagious or infectious nature), the point to which it is to be shipped, medical attendant, and name of undertaker."

Rule 6 refers only to the "transit permit."

"Rule 7.—The box containing corpse must be plainly marked with paster, showing name of deceased, place of death, cause of death, and point to which it is to be shipped, number of transit permit issued in connexion, and name of person in charge of the remains.

"Rule 8.—Disinterred bodies, dead of any disease or cause, will not be accepted for transportation unless said removal has been approved by the state board of health, and the consent of the health authority of the locality to which the corpse is consigned has first been obtained, and the disinterred remains, enclosed in a hermetically sealed (soldered) zinc, tin, or copper lined coffin or box, encased in hermetically sealed (soldered) zinc, tin, or copper cases."

Mr. Edward Barker.—We are unable to understand the enclosure, unless the gentleman named is distributing the cards wholesale.

A COMPLAINT.

To the Editors of THE LANCET.

SIRS,—I enclose herewith a cutting from the *Echo* of to-night's issue. The writer describes himself as an aural specialist, and answers correspondence in the columns of the paper. Mr. Passmore Edwards as a philanthropist claims that the profits of his paper are spent in founding hospitals and libraries, &c.; but surely he is inconsistent in making the *Echo* the recognised organ of quacks and faddists and allowing such attacks as the enclosed to be made upon an honourable profession.

I am, Sirs, yours truly,

Sept. 3rd, 1897. LAUNCELOT ARCHER.

*** The cutting referred to is a letter signed "Lennox."—ED. L.

M.R.C.S., L.S.A.—We are obliged to our correspondent for his information, but the matter being still *sub judice* we cannot comment upon it at present.

Surgeon (Liverpool) has omitted to enclose his name and address.

Digitized by Google

"URBER" COMBINATION.

THAT suitable and sensible or, as manufacturers prefer to style it, "hygienic" clothing is of the first importance to health is recognised now by all medical men; but in our climate it is sometimes difficult to devise garments adaptable to a rapidly changing environment. For example, at the present time many people want a wrap that will withstand heavy rain, but which will not by its weight retard the easy motion of the body or by its substance prevent free perspiration. Messrs. T. Burberry and Sons, of 30, Haymarket, S.W., have devised a process of treating light materials to meet these requirements. By this process each separate fibre of the materials is "proofed" so that rain stands on it in beads like quicksilver, ready to be shaken off at the first movement, but a certain amount of passage of air between the fibres takes place. It follows that it is possible to force water through the material, though it is impossible to make the cloth soak it up and become sodden, heavy, and not only uncomfortable, but dangerous. The specimen coats sent for our inspection were lined with a light silk lining, "proofed" by the same process as the homespun. We have tested the garments thoroughly and have found them useful under the circumstances indicated, when heavy ulsters or mackintoshes would be burdensome and uncomfortable.

A. F. M.—(1) Yes. (2) It would have to be written for. (3) There is no regular agent we fancy, but probably Messrs. Baillière, Tindall, and Cox would procure it.

"NOTE UPON THE TOXIC EFFECTS OF THE SWEAT OF A HEALTHY MAN."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Sept. 4th appeared a translation from *Comptes Rendus* of a paper by M. S. Arloing on the toxicity of normal human sweat—a subject which has latterly engaged the attention of many continental writers. In the Spanish medical journals numerous contributions appeared. *El Siglo Medico* of Aug. 22nd had a short but excellent annotation on "Human Sweat," in which the following quotation from an old Latin writer appears: "Take the sweat of a horse from between the ribs of the right side, and with this wet the puncture of a lancet; this wound will be mortal. This action has been performed with desired results."

I am, Sirs, yours truly,

Cavendish-row, Dublin, Sept. 4th, 1897. GEORGE FOY.

An Old fashioned Physician has forgotten to enclose his name and address.

G. S. (Guernsey).—We are unable to help our correspondent. He must consult his own medical man.

A DUEL BETWEEN MEDICAL MEN.

AN armed encounter between members of the medical profession at this the close of the nineteenth century was certainly not to be anticipated, but the old saying that it is always the unexpected which arrives has once more been verified. It is only too true that a duel was recently fought at Bonn, the combatants being both medical practitioners, and most unfortunately one of them met with his death from a penetrating wound of the thorax. It seems that two of the assistants at a surgical clinic, named Reusing and Fischer, had a violent altercation over a professional matter, the former accusing his colleague of malpractice in the conduct of an operation, and as apparently there was no older and wiser person at hand to pour oil upon the troubled waters a hostile meeting ensued, with the above-mentioned deplorable result. That duels should still survive on the Continent, especially in military circles, is, perhaps, not to be wondered at under the existing régime, but happily the vast majority of medical men of all nationalities are the possessors of well-balanced minds, and recourse amongst them to the *argumentum baculinum* for the adjustment of technical disputes must be an altogether exceptional occurrence. Complaints are often heard of the overcrowding of the medical profession on the other side of the Channel, but of all depletory methods the slaying of one's *confrère* is surely the least philosophical. A duel at the present day is an anachronism. As a mode of settling scientific controversy it is not only out of date, but also about the most illogical procedure conceivable. Killing an opponent does not prove the survivor's case; while the gratification of an ignoble feeling of personal resentment is dearly purchased at the expense of life-long remorse. The principals in a duel are, of course, blameworthy, but for them there are excuses, seeing that most human beings are more or less passionate by nature. For the seconds, generally speaking, there is absolutely nothing to be said. They are simply the abettors of a crime in which they run no bodily risk, and it is against them that retributive justice should be mainly directed. If seconds would only consider the heinousness of their position there would soon be an end of duelling.

A FRENCH MEDICAL DICTIONARY.

A CORRESPONDENT writes to us in answer to Mr. Hay Forbes's query:—"Mr. Hay Forbes will find the 'Terminologia Medica Polyglotta, edited by Dr. Theodore Maxwell (London: J. & A. Churchill, price 16*s.*), a very useful book for his purpose."

S. F.—The builder ought to pay with many thanks for the prompt attention. Whether the fee can be recovered from him is another matter and depends wholly on the view a county court judge would take of the question of agency—i.e., whether the workman who called our correspondent was or was not the agent of the builder. One judge might think he was such an agent, another might hold a contrary opinion. That the builder ought to pay is certain.

R. M.—Barnard and Stocker, Medical Partnerships, &c. (London: Stevens and Son), price 10*s.* 6*d.*

L.R.C.P., &c.—Our correspondent has not enclosed his name and address.

ERRATA.—In the Student's Number of THE LANCET published on Aug. 21st, page 445, col. 1, line 70, the word "sixth" should be *seventh*. On page 442, col. 1, line 5, "1895" should read *1896*.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (13th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (14th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (15th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.).

THURSDAY (16th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.).

FRIDAY (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (18th).—Royal Free (9 A.M. and 2 P.M.), Middlesex, (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

During the week marked copies of the following newspapers have been received:—*Greenock Telegraph, Cork Examiner, Hereford Journal, Manchester Courier, Whitehaven Free Press, Court Circular, Science Siftings, Blackburn Times, Lincolnshire Echo, Edinburgh Evening Dispatch, North-Eastern Daily Gazette, Scotsman, Norfolk Standard, Times of India, Pioneer Mail, Birmingham Daily Gazette, Glasgow Herald, Sheffield Independent, Darwen Post, Bristol Mercury, Architect, Preston Herald, Bedford Times, Builder, Bradford Argus, Leytonstone Independent, Devon Weekly Times, Sussex Daily News, Keen's Bath Journal, Bolton Chronicle, Liverpool Daily Post, Luton Reporter, Leighton Buzzard Reporter, Tottenham Herald, Yorkshire Post, Leicester Post, Bexhill Chronicle, Cheltenham Mercury, Observer and Chronicle (Bournemouth), Carnarvon Herald, Bridgwater Independent, Walsall Advertiser, Evesham Journal, Surrey Comet, Portsmouth Times, Newcastle Leader, Norwood Review, Dunstable Advertiser, Leeds Mercury, Salisbury Journal, Brighton Gazette, Buxton Herald, Jarrow Express, Banffshire Herald, Bazaar, Sanitary Record, Western Daily Mercury, Mining Journal, Reading Mercury, Hertfordshire Mercury, Public Health, Local Government Chronicle, Weekly Free Press and Aberdeen Herald, City Press, Brixton Free Press, Gazette (Montreal), Local Government Journal, Surrey Advertiser, Eastbourne Gazette, Sussex and County Herald, Daily Telegraph (Launceston), Swindon Advertiser, The Journal (Carmarthen), Evening Star (Ipswich), West Middlesex Herald, Keighley Herald, Sussex Coast Mercury, &c., &c.*

The Action and Uses of some New Medicinal Agents.

ANTIPYRIN.

(PHENYL-DIMETHYL-PYRAZOLONE.)

THE question regarding the importance of the therapeutic action of antipyrin and other drugs allied to it in action and in structure was referred last year to the Therapeutic Committee of the British Medical Association. The report indicated that a large amount of practical experience had been obtained concerning the nature and action of antipyrin and its harmlessness when administered with due regard to suitability of dosage and case. Upon its first introduction it was mostly used as an antipyretic, but a consensus of later opinion showed unmistakably that its principal therapeutic value lay in its effects as a minimiser or remover of pain.

While the information which the committee obtained regarding the nature of any ill effects of this drug was of the greatest theoretical importance, the practical objections to its use were of slight moment, being due principally to an excessive physiological action of the drug probably induced by errors in its administration.

Antipyrin is a drug capable of relieving intense neuralgic pains of functional origin with a completeness which demonstrates that it possesses a very powerful action on the nervous system and through that on the metabolic processes of the body. As an analgesic it is especially active in relieving those pains occurring in paroxysms or which are caused by nerve storms. It proves an active analgesic when pain is due to alterations in the posterior column of the spinal cord, as in the severe lightning pains of locomotor ataxia. It is not accurately ascertained how this action comes about, but it has been supposed that Antipyrin acts by distributing sensory impulses over a greater number of brain cells, so that the initial impulse which gives rise to the pain is, as it were, modified by being spread over a larger receptive area, and is thus diminished or even lost.

Other pains of a spasmodic character—such, for instance, as in sciatica, migraine, colic, and some forms of dysmenorrhœa characterised by spasmodic paroxysms of pain—are greatly ameliorated by the action of this drug.

Another group of diseases which comes under its influence includes those which are dependent upon nervous irritation or excessive excitability of the motor nerve centres, such, for instance, as croup, chorea, and whooping-cough, in all of which antipyrin has a sedative action on the irritable nerve cells. In combination with the bromides its effect is said to be enhanced in such disorders as enuresis. Other nervous disorders of the bladder also have been treated successfully with antipyrin.

As a febrifuge, antipyrin reduces febrile temperature with great rapidity when it is not due to inflammatory processes. It dilates peripheral cutaneous vessels, and thus increases radiation. It also lessens the production of heat, and further diminishes temperature by allowing radiation and by the evaporation of the perspiration which it produces on the skin. It does not, however, act powerfully as a sudorific, but slightly increases the blood pressure. The temperature will remain reduced under the action of antipyrin for from one to twenty hours. Any subsequent recrudescence of fever is not accompanied by marked rigor. It is therefore of great value in many of the specific fevers, especially in typhoid and phthisis, but it has also a powerful effect in reducing the temperature in erysipelas, surgical fever, and in many cases of pneumonia.

Antipyrin has been used also as a hæmostatic in a 4 to 5 per cent. aqueous solution. It can be injected subcutaneously in half its weight of water, and seems to have a special action on the fifth nerve in severe facial neuralgia. It gives a deep red colour with a solution of perchloride of iron, is incompatible with spiritus ætheris nitrosi or nitrites, with which it forms an inert bluish green compound. It is also incompatible with quinine, and liquefies with butyl-chloral-hydrate, salicylate of sodium, and β naphthol.

"Tabloid" Antipyrin is supplied in two strengths—2½ grain, sugar-coated, supplied to the medical profession in bottles of 24 and 100, at 8d. and 2s. 1d., and 5-grain in bottles of 25 and 100, at 1s. 1d. and 3s. 11d. per bottle.

AGATHIN.

(SALICYL-ALDEHYDE α-METHYL-PHENYL-HYDRAZONE.)

Since it was originally discovered by Dr. Ross this drug has been tried with much success as an anti-neuralgic and anti-rheumatic, and found effective when other agents have failed. Recent testimony proves undoubtedly that Agathin may be administered with advantage in obstinate cases of sciatica that have resisted other treatment, the pain being speedily and permanently removed. In both articular and muscular rheumatism, also, Agathin has been prescribed with very satisfactory results when salicin, salicylates, sulphur, and the usual run of remedies produced little or no effect. "Tabloid" Agathin, 4 grains, preserves the full efficacy of the drug, two thrice daily being a fair average daily dose for adults. Supplied in ½-oz. and 1-oz. tins at 9s. 3d. per oz.; also "Tabloid," 4-gr., in bottles of 24 and 100, at 2s. 8d. and 10s. per bottle.

ALUMNOL.

(ALUMINIUM-NAPHTHOL-SULPHONATE.)

The physiological action of alumnol is that of a harmless, odourless, antiseptic and astringent, which is capable, by reason of its solubility, of exerting a penetrating effect. It may thus be substituted advantageously for the antiseptic astringents hitherto in vogue—for example, nitrate of silver—which are effective only at the surface of contact, because they form insoluble compounds with the albumen of the uppermost cellular layer of the exudation. Alumnol is the aluminium salt of a naphthol-sulphonic acid, containing 15 per cent. of sulphur in the form of the sulphone group and about 5 per cent. of aluminium. It forms a white powder which is very readily soluble, even in cold water (40 per cent. solutions may be made without separation of the salt as standing); it is also taken up by glycerine and hot alcohol, the solution in the latter solvent exhibiting a beautiful blue fluorescence. Alumnol supplied to the medical profession at 1s. per oz.; also "Soloid" Alumnol, 4-gr., at 8d. and 1s. 6d. per bottle.

BENZOSOL.

(GUAIACOL-BENZOATE.)

It is odourless and tasteless, and yet retains all the valuable properties of creosote; it must, therefore, be regarded as a real and important step forward in the medical treatment of tuberculosis. The results obtained by benzosol have been at least equal, if not superior, to those yielded by creosote. The action of the drug is shown by the relief and decrease in violence of the tormenting fits of coughing; expectoration is lessened in quantity and hectic perspirations disappear. Appetite and the general condition of health steadily improve. Benzosol may be regarded, therefore, as an agreeable and harmless substitute for creosote, beneficially influencing the general nutrition, and consequently increasing the resistance of the patient to the disease. Benzosol is supplied to the medical profession at 3s. 3d. per oz., and "Tabloid" Benzosol, 5-gr., in bottles of 24 and 100, at 1s. 4d. and 4s. 8d. per bottle.

HYPNAL.

(MONOCHLORAL-ANTIPYRIN.)

Fifteen grains of this substance have been found equal in hypnotic effect to 7½ grains of chloral hydrate. It is nearly tasteless and devoid of qualities irritating to the mouth or stomach. It is considered an unrivalled soporific when insomnia is the result of pain or of mental excitement, incipient delirium tremens, or chorea. It is supplied to the medical profession at 2s. 11d. per oz., also "Tabloid" Hypnal, 5-gr., in bottles of 24 and 100 at 1s. 2d. and 4s. 4d. per bottle.

The above are produced by the Farbwerk vorm. Meister, Lucius, & Brüning, Hoechst-am-Main, and specimens may be had, as well as literature bearing on these and other new remedies, upon application to the agents,

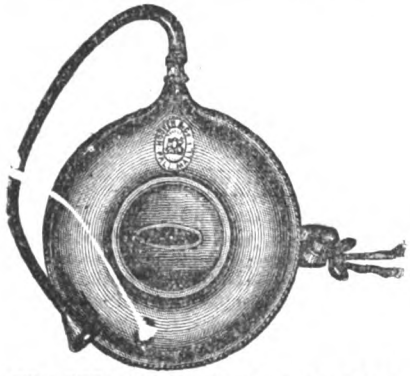
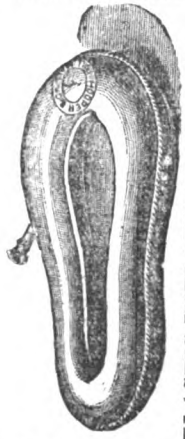
HOOPER'S ELASTIC WATER OR AIR BEDS AND CUSHIONS.

To be used on any ordinary Bedstead or Couch.

For Paralysis, Fevers, Consumption, Rheumatic Affections.



For Sale or on Hire.



For Bedsores, Spinal Affections, and all Bedridden Patients.

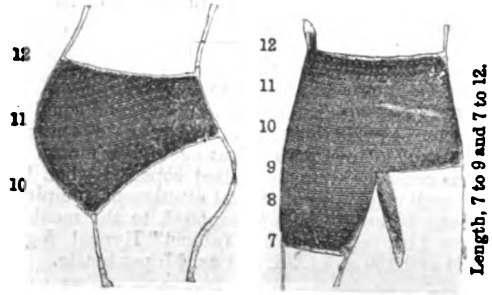
HIGHEST AWARD AT THE INTERNATIONAL MEDICAL AND SANITARY EXHIBITION, 1881

☞ Messrs. Hooper & Compy. beg to invite the attention of the Profession to their system of hiring their Water Beds otherwise than in contagious or infectious diseases, and feel assured that where outlay is a consideration the Profession will appreciate and avail themselves of this hiring system.

ELASTIC INFLATING BED PAN.

ELASTIC INFLATING BED SLIPPER.

SANITARY BED PAN.

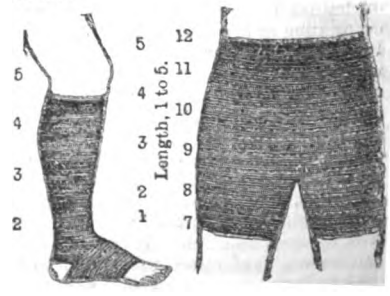


IN WHITE PORCELAIN OR GUTTA PERCHA.

Fitted with lid and stopper to prevent effluvia when removed from the Patient.

The Elastic Bed Slipper and Bed Pan, from their softness and elasticity, are peculiarly adapted to Ladies after confinement, and to Invalids who, from emaciation or other causes, cannot bear the hardness of ordinary utensils.

HOOPER'S SPIRAL ELASTIC BANDAGES.



POROUS—ALLOWING FREE VENTILATION.

The measure should be taken next the skin, as follows:—

1, Round thickest part of instep.
2, Round ankle-bone.
3, Round small of leg.
4, Round thickest part of calf.
5, Round leg, just below knee.
6, Round knee-cap.
7, Round leg, just above knee.
8, Round middle of thigh.
9, Round top of thigh.
10, Round body at hips.
11, Round body at umbilicus.
12, Round waist.

The length should also be given.

Experienced Male always in attendance for fitting Trusses, Belts, and Stockings.

SOLE PROPRIETORS AND MANUFACTURERS,

HOOPER & COMPY., 7, Pall Mall East, & 55, Grosvenor St., LONDON.

ORDERS BY POST OR TELEGRAM EXECUTED IMMEDIATELY.

SPECIAL DISCOUNT FOR POOR-LAW GUARDIANS.

ABSTRACT OF THE

Inaugural Address

Delivered at the Sixteenth Congress of the Sanitary Institute at Leeds on Sept. 14th,

BY ROBERT FARQUHARSON, M.D. EDIN., LL.D. ABERD., F.R.C.P. LOND., M.P.

GENTLEMEN,—My feelings on rising to address you this afternoon are somewhat mixed, and I venture, although not very confidently, to hope that I may be able to use this platform as an authoritative tribune from which to speak words which may be suggestive if not weighty. Such an opportunity probably only occurs once in a lifetime, and it may well be a subject for anxious reflection how best to use, without abusing, the indulgence of the influential audience I see before me. But other considerations have urgently claimed my attention since Sir Douglas Galton first whispered into my ear the tempting offer of this presidential chair, and as this day drew nearer they also came nearer to my mind.

The responsibility of an introductory orator on such an occasion as this is much increased by the fact that hygiene has now become fashionable, and that most people nowadays know at all events the elementary principles on which it works. All great subjects like this, and more especially those which involve some dislocation of antiquarian superstition and domestic prejudice, must pass through a variety of stages or cycles, and varying waves of interest beat on the mental shore.

First, we have the stage of ridicule, a difficult one to get over, but which we have at last successfully surmounted. Next we find that when the general public recognise that we are in earnest the stage of active opposition sets in, and vested interests and pig-headed ignorance, and the self-complacent argument of "why not let it alone," are marshalled in warlike array against the new broom which tries to sweep the Augean stable clean. But we have now nearly outlived all this; ventilators are no longer stuffed up, the working classes, no less than their employers, are beginning to be connoisseurs in the quality of their atmospheric conditions, enjoy a good wash as much as a university graduate, and are fully prepared to appreciate the advantages of hygienic house accommodation at other people's expense. Associations like our own, and the National Health Society, and the St. John Ambulance Association, and able and zealous missionaries, have not spoken and written in vain, and now we live in an age of sanitary progress, where the little knowledge, which is safe not dangerous, persuades its possessor of its scanty amount, and tells him where to go to make good his deficiencies. For instance, no properly instructed person in these enlightened days would take a house without a thorough inspection of, and report on, its sanitary arrangements; water analysis and food analysis keep us fairly free from adulteration, and most of us know pretty well, or at all events know how to get the information, as to the amount of help given us by the law in keeping our health fairly sound. For the conclusion is inevitable that the race is to the swift and the battle to the strong, and that unless we are well equipped physically for the contest we will be outpaced and shoved aside, and laid on the shelf. The well-worn quotation from Herbert Spencer sums up the whole case: "The first requisite of life is to be a good animal, and to be a nation of good animals is the first condition of national prosperity."

[Dr. Farquharson here regretted the monotony of modern labour, which, he suggested, is largely due to the minute subdivision of employments. He then made some reference to recent advances in physiological knowledge and continued:]

Some will probably ask this question: "It is all very fine talking about fashion and popularity and progress; can you show any tangible results? Is the human race any longer lived, or better, or happier at present than in the good old days of pre-hygiene?" Now if any lingering shade of romantic leaning towards the life conditions of mediæval or post-mediæval England still haunts your mind, you may lay the ghost by diligent perusal of Simon's "English Sanitary Institutions" and the "Health of Nations," in which the work of Edwin Chadwick is reviewed by Richardson—that bright and kindred spirit; and I guarantee that even if imagination still gilds the remote history of the past you will thank your stars that your lines have been cast in the cleaner and pleasanter places of the Victorian era. There is no doubt that the average sum of life has been sensibly prolonged. During the last quarter of a century the death-rate has been reduced from about 22 to 18 per annum, and whilst I give you sanitarians your full meed of praise for having, by your excellent work, abolished some diseases and lessened the incidence of others, we medical men intend to claim some credit too. We diagnose disease earlier and treat it far better, making much less demands on the constitutional vigour of our patients, and keeping in mind the good old principle that prevention is better than cure. For the future let Professor Matthew Hay, of Aberdeen, speak. He writes to me: "Progress of the death-rate downwards must in the future be less than in the past. A death-rate of 10 per 1000 would mean that everybody born lived to 100 years or an average of that. Probably it will be found that the mutual elements of decay in men, as in all living things, which make eventually for death, independently of environment, will not permit of a lower general death-rate than about 14 to 15 even under the most favourable hygienic conditions reasonably attainable. So that by the time we have gone as far in reducing the death-rate as we have come in the past quarter of a century we shall have reached the ultimate minimum, but it will certainly not be in another quarter of a century." More evidence can be found in the Reports of the Local Government Board, where, under the skilful guidance of Sir John Simon and Sir George Buchanan and Sir Richard Thorne Thorne, some of the most acute minds in England have been unravelling abstruse sanitary problems and tracking out from clues invisible to the ordinary eye sanitary defects which were poisoning districts and destroying human life. But these are scattered and not always accessible, and I strongly commend to your attention two capital little books which strike the nail very directly on the head. The first of these is by your respected townsman, Mr. Pridgin Teale, who, in the intervals of a brilliant and successful surgical career, has found time to preach the doctrine that a nation's health is a nation's wealth, and to furnish a series of object lessons of the most clear and practical if alarming kind. The second is by our esteemed friend and associate, Professor Corfield, one of the pioneers of sanitary progress, and it is called "Disease and Defective House Sanitation." It consists of two short lectures, but it is crammed with suggestive matter, and he enumerates the following diseases as directly caused by the defects included in his title—sore throats, diphtheria, scarlet fever, blood poisoning, puerperel fever, pneumonia, diarrhœa, enteric fever, and general malaise. All these have resulted from badly-connected ventilating pipes, badly-trapped waste pipes, defective drains, split soil pipes, foul pan water closets, and very frequently from escapes of gas, a cause more especially of sore throats, new to me, I must confess. May I give you one other illustration? I think it was in 1884 or 1885 that serious complaints began to be made about the drainage and ventilation of the House of Commons. A committee was appointed under the presidency of Sir Henry Roscoe to examine the whole question, and we had to tell the legislators on the basis of a very important investigation by the late Professor Carnelley, that they were actually breathing sewer gas, and that the sooner they put their house in order the better for themselves and the country. So £10,000 were voted *nem. con.*, Shone's ejector cut us off from the main sewer, and I make so bold as to claim for this sanitary operation national importance in improving the health and temper of our senators and enhancing the quality of their work.

The benefits conferred by modern civilisation are, however, accompanied by some drawbacks. In the seventeenth century the death-rate was said to be 7 per cent.; it is now about 18 per 1000, the advantage being mainly between the ages of five and thirty-five, and our chances of reaching this maximum period of longevity are distinctly increased. The majority of us, however, are older than that, and we want to know what is to become of us, and vital statistics do not give us much comfort, for after middle life, when we stand on the tableland and look over the edge, before stepping downhill, we do not live longer and we break down sooner. Why is this? One evil of civilisation is the tendency to crowd into big towns, where houses are dear and often bad, the air is usually poisoned with smoke, and, as Dr. Poore has well shown in his most interesting work on Rural Hygiene,

Digitized by Google

there are serious dangers connected with defects in our complicated arrangements for drainage and sewage disposal. This is depressing, but it has its bright side. No doubt it is dangerous to be placed within easy reach of receptacles of foul air and sewer gas, as we all are, and necessarily must be, under the system of water-borne sewage common to our great towns; but the greater the risk the greater should be the care exerted to keep it off. It would be a good thing if workmen, and more especially those who manufacture the complicated structures which modern hygiene requires, should not only feel but carry into practice the full sense of responsibility resting on them in connexion with their trade; and that they should be taught how a bit of scamped work—a leaking cesspool, or a badly placed or constructed drain, or a badly-socketed soil-pipe, or any derangement in the mechanical contrivances designed to keep out the sewer gas which is always trying to force its way in—may destroy human life just as effectually as poison or the knife. This is why I have persistently supported the Plumbers' Registration Bill in and out of Parliament, being convinced, as I am, that without establishing a monopoly, or doing any real harm to any vested interest, the establishment of a defined curriculum, followed by registration and examination, will raise the status and character of the workman, and by increasing his sense of responsibility and his interest in his work will not only confer benefits on him, but also on those by whom he is employed.

The next point I wish to refer to is the curious way in which, when we have abolished one set of diseases, another band of successors sometimes springs up hydra-headed to plague poor humanity. I suppose it must be so, for we poor mortals have not put on immortality, but must shuffle off our mortal coils, in some swift or lingering way, so that if we are prevented from dying from one disease we must of sad necessity die from another, and diminution of one death-rate involves increase somewhere else. Enteric fever remains pretty stationary in the last ten years, but a drop from 309 in 1876 to 175 in 1895 does credit to our sanitary administration, and phthisis has gone down from 26,443 in 1876 to 22,775 in 1894. Small-pox has taken a satisfactory dip downward from 2405 in 1876 to 33 in 1895. Measles, scarlet fever, and whooping cough have killed fewer than formerly, but, *per contra*, diphtheria has largely increased, and that is no doubt due, as Sir R. Thorne Thorne says in a private communication which I have received from him, "to the ever-growing facilities for personal infection, and other similar points have followed on the success in herding our child population into elementary schools at the very age at which they are most susceptible to this disease." Other diseases have also increased, and the point I wish to make is this, that they are mostly diseases connected with the nervous system, and that Crichton Browne was probably right in his opinion that not merely the nervous temperament, but the neurotic diathesis is on the increase among us. To begin with, it is a mournful but I fear an undoubted fact that more people go mad than formerly. I have not by me any statistics to prove this beyond the report of the Registrar-General for 1895, but there I find under the heading of insanity and general paralysis—a disease which was seldom heard of in former years—3620 deaths in 1895, against 933 in 1876.

Angina pectoris, a typically neurotic disorder, has increased within the same period from 397 to 696; valvular disease of the heart, which has some practical sympathy with the neurotic diathesis, has gone up from 274 to 10,072; whilst Bright's disease, the frequent causation of which by sudden mental shock has been demonstrated by Clifford Albutt, shows an alarming rate of increase from 4100 to 8351. Cancer has nearly doubled since 1876, and diabetes reached its highest point in 1895, accounting for 2265 deaths over 910 in 1876, whilst most of us know only too well the firm grip taken by influenza on the British constitution, and the way in which in more recent years it has attacked the nervous system. There seems no doubt, therefore, about the fact that we are now in the midst of a neurotic age, and, moreover, an age which is essentially anæmic. How many young girls in any rank of life escape passing through a bloodless stage, which suggests a strike or a lock-out among their red corpuscles, and a consequent stagnation of their vital processes?

Let us take another glance at the Registrar-General's report, where we will see that deaths from anæmia, chlorosis, and leucocythæmia have advanced from 576 in 1876 to 1883 in 1895, and this, together with a glance at the cheeks of the rising generation, must convince you that this increase of pallor is only too real.

[Dr. Farquharson here remarked that he wished to say a word in favour of sexual selection, commending the Vicar of Wakefield for choosing his wife as she chose her wedding-dress—"on account of her wearing qualities." With respect to vaccination, he suggested that the age should be raised so as to avoid the teething and eruptive periods, and that every infant should have four good marks, the operator being preferably a public vaccinator. He then referred to school life and house accommodation, and concluded as follows:]

Each of us is individually responsible to ourselves and to others for our scheme of sanitation, and then we pass into the hands of local authorities, who are doing good work, who generally give you value for your money, and whose beneficial operations I hope you duly appreciate. But over them stands the House of Commons, and I am glad of this opportunity of saying that I have a very poor opinion of that legislative assembly in its dealings with public health. Both sides are bad, but that to which I belong is, I think, the worst, for suspicion of scientific methods and of progressive sanitation is deep-rooted in certain Radical quarters, and abstract views of personal liberty and distrust of the so-called tyranny of medical men sway a kind of plausible sentiment which is usually irresistible in its paralysing effects on hygienic legislation. As a Member lately remarked with refreshing frankness when we were considering the Public Health (Scotland) Bill, "When I see the doctors on both sides of the House my instinct tells me that something is wrong and I will vote against the amendment." Under such conditions the private Member can do nothing, beyond being usefully employed in stimulating public opinion in and outside the House, until particular problems reach the acute stage and are taken under Government protection. In conclusion, let me reiterate the strong wish I have already publicly expressed in favour of a Ministry of Health, a department of the State which would collect into one harmonious whole the scattered threads of sanitary legislation, which would focus all health questions, and admission to which would be an object of honourable ambition to the best scientific talent of the day.

ABSTRACT OF A

Post-Graduate Address

ON

THE MEDICAL ASPECTS OF APPENDICITIS.

Delivered at the West London Hospital on Feb. 3rd, 1897.

BY DONALD W. C. HOOD, M.D. CANTAB., F.R.C.P. LOND.,

SENIOR PHYSICIAN TO THE WEST LONDON HOSPITAL.

GENTLEMEN,—That form of local peritonitis so frequently met with in the right iliac fossa and known under the various names, typhlitis, perityphlitis, or appendicitis, presents numerous features of interest both to the physician and the surgeon. I have thought that it might be useful on the present occasion to discuss the disease from its medical aspects alone, for while fully acknowledging the brilliant achievements of surgery in connexion with abdominal diseases, I have no hesitation in affirming that we are in danger of looking upon the treatment of appendicitis from a too exclusive point of view, and I fear that many, by forgetfulness of the good results which follow a purely medical course of treatment, lose the valuable opportunities which only come to those who see the disease at the earliest onset.

In considering the diagnosis of appendicitis we must first glance at the forms or varieties under which the disease is met with, and we must consider briefly those affections with which it is liable to be confounded. We meet with appendicitis in one of two principal forms—namely, (1) an acute

Digitized by Google

peritonitis due to sudden perforation of the appendix, and (2) localised inflammation in connexion with the cæcum or appendix.

The first variety is happily rare, and I believe is in many cases akin to that form of perforation met with in gastric ulcer and latent typhoid fever. During twenty-five years' fairly active work I have never met with such a case either in private or hospital practice, and I doubt whether such perforation ever occurs without some premonitory symptoms. These cases are usually met with in the post-mortem room, and they may come there without a correct diagnosis, but this scarcely proves that symptoms were entirely absent. Some individuals, however, have an exceptional power of withstanding the constitutional disturbances of severe diseases, this tolerance of disease being especially marked in latent typhoid fever, and in acute perforating gastric ulcer. Hence it is possible for perforation of the appendix to take place even where those symptoms which we consider to be pathognomonic of the condition are latent, if not entirely absent. The following case proved to me that well-marked objective symptoms may be present without producing much constitutional distress. A medical friend called upon me one afternoon, stating that he had not been feeling well for some days, and I was surprised to find the iliac fossa occupied by a large tumour. Within a few hours of seeing me he was examined by a surgeon, who subsequently informed me that he looked upon the tumour as being malignant. However, a few days' rest in bed and opium as a remedy restored my friend to perfect health, and there has been no recurrence of abdominal trouble.

The second or more ordinary form of appendicitis can be subdivided into many clinical states, but I doubt if we gain much by such subdivision. We have clinically to consider two main conditions of localised inflammatory mischief within the right iliac fossa, one with tumour and one without. In other words, the inflammatory mischief may be circumscribed or more diffuse. The first and by far more usual condition can only be overlooked or misinterpreted through carelessness or ignorance; the other form, however, is much less common, and the symptoms are frequently liable to misinterpretation. A good instance of this variety came under my notice last year. The patient had gone to church on a Sunday feeling well; after the service she felt poorly, and it was thought that she had been chilled, the wind having been specially keen and penetrating. That night she was seized with sharp abdominal discomfort and diarrhœa, which continued during the following day, the temperature running up to 101° F. She was given a "dose," but the pain, pyrexia, and diarrhœa continued for the next four days. It was on the evening of the fourth day, that I first saw the patient. She looked very ill, had a small, rapid pulse, raised temperature, dry red tongue, and frequent diarrhœa. The abdomen was flat, and there were no rose spots. Extreme pain was felt on making light pressure on the right iliac area. No tumour could be detected. It appeared to me that the balance of clinical evidence was in favour of the attack being due to local trouble rather than to specific fever. The following day a pultaceous blood-stained stool was passed. The patient was still in a very critical state. The diarrhœa had ceased, there was pain in the iliac fossa, but no tumour or thickening. The next morning on making careful pressure over this area there was decided resistance, giving the sensation of infiltrated tissue. The condition of the patient then improved, and she made a complete recovery, but from first to last there was no decided tumefaction of the part.

The ordinary form of appendicitis as met with in hospital patients is unattended with much difficulty as regards diagnosis, because the disease is well developed and past the primary stage of initial onset, but with private patients the case is different, and more often than not we have the opportunity of investigating the symptoms of the attack within a few hours of their commencement.

The first symptom is pain, which may vary in amount from extreme pain, almost agony, to mere abdominal discomfort. As far as my experience serves me, commencing appendicitis is invariably attended with some rise of temperature. In the larger proportion of simple abdominal ailments attended by pain there is no rise of temperature; but abdominal discomfort with diarrhœa and raised temperature has been far from unusual with certain forms of influenza, and this fact must be kept in view. If, then, in any patient who complains of aching in the abdomen we find a raised temperature, it is necessary to carefully examine the part. This cannot be properly done unless the patient is undressed and lying down. Even in the earliest stages inspection will often give us assistance; aided by good light you will at once be struck by the absence of movement over the affected area. The portion of the abdominal parietes lying between the ribs and the pelvic crest moves but little if at all during respiration. This want of muscular action is far more evident later, but it will be present at first in some degree. I have often been able to demonstrate the absence of movement when not easily detected by the eye by placing on the part a long lever such as a stethoscope. In the first few hours of illness pain, with even but a slight rise of temperature, should be sufficient to place us on our guard, and when, after baring the abdomen, immobility of the part is seen, it is almost pathognomonic of the specific nature of the attack, and scarcely renders necessary the putting to proof the presence of the fourth symptom—tenderness on palpation. In recent years much stress has been laid upon the limitation of pain to one spot, the so-called "McBurney's point," but I prefer to trust to the general conditions rather than to any one limited point of more decided pain than another. Far more help will be given by placing the palm of a warm hand upon the abdomen. Gentle pressure over the iliac fossa will in ninety-nine cases out of a hundred give all the information required, and will be far less likely to lead to error than if the tips of the fingers are pressed into a part which is even in many normal individuals exceedingly sensitive. As time measured by hours passes on we shall find evidence of resistance, thickening of deep parts, and finally tumour, which may in some cases encroach largely upon the abdominal cavity. The whole abdomen may become swollen and tender. The early stage of fever plus abdominal tenderness is well shown in the following case. A girl, aged nine years, had suffered from a sharp attack of appendicitis in December, 1881. On Jan. 15th, 1882, her nurse found her crying in bed and complaining of stomach ache. The child had gone to bed apparently in perfect health and had completely recovered from a previous attack. When seen by me within an hour of the first complaint I found tenderness of the iliac fossa and a temperature of 100° F. The attack was a severe one, the temperature fluctuating between 101° and 103° for eight days. The bowels acted on the ninth day. The patient made a perfect recovery and since the illness has had no return of abdominal trouble.

In addition to the four cardinal symptoms of appendicitis, the pain, fever, local tenderness, and immobility of abdominal walls, there are other symptoms which attend the progress of the attack, the most common being vomiting. I find that in 308 cases this symptom was specially noted in 208 patients. It is a symptom which forebodes neither good nor evil. Appendicitis may be complicated by either constipation or diarrhœa; the former occurred in 145 patients out of 308, the latter (diarrhœa) in 58 patients out of the same number. The presence of diarrhœa in the early stage frequently leads to an erroneous diagnosis, so that it is well to bear in mind this not unusual state of bowel. Of the 58 cases in which looseness of bowel was present, 43 made good uncomplicated recoveries and 3 recovered with abscess. Nine patients died; of these 2 succumbed to general peritonitis and 7 suffered from abscesses.

Some writers make a distinction between those attacks of local peritonitis which are accompanied by exudation of coagulable material but in which the symptoms pass away with more or less rapidity, and that class of cases where the inflammatory mischief leads up to the formation of pus. Clinically I believe it to be absolutely impossible to distinguish between these two classes of case in their earlier stages, and I think it is equally impossible to say whether or not they have the same pathological cause. On this point our hospital cases afford us but little assistance. These patients being admitted at every stage of their illness, any mortality-rate obtained from a series of cases is grossly misleading as to the direct effect of treatment. Dr. Eyre has very kindly and with great care and labour examined the medical records of Guy's Hospital between the years 1867–1895, and has tabulated for me all the cases of appendicitis admitted as such during that period. Thus among 308 cases admitted during twenty-nine years fifty-five patients died. But when these individual cases were examined we found that in a large proportion the patient died within a few hours of admission, and many were admitted after the formation of an abscess. Such statistics

Digitized by Google

are of almost no value as indicating the efficacy or the disadvantages of any line of active treatment.

My experience of surgery in connexion with appendicitis is *nil*; every case that has come under my care has hitherto made a complete recovery, with the solitary exception of a man admitted into the North West London Hospital some years ago suffering from a second attack. He was admitted with symptoms of general peritonitis and an operation was not considered advisable. He had apparently quite recovered from the primary attack. The treatment adopted before admission had been that of purging.

The onset of the affection varies much—it may be acutely sudden or creep insidiously on for several days. The following history is of value as it comes from the hand of a medical man who placed himself under my care in May, 1894. The patient stated: "On getting into bed I was suddenly seized with shivering and vomiting; my temperature was 100 6° F. The abdomen generally was tender. I passed a very restless night, nausea and retching being continuous. Abdominal pain was acute, but so far not localised. The temperature was 101°. During the day symptoms were much the same. During the second night the pain became localised in the right iliac fossa and the diagnosis was clear." I saw the patient on the third day of illness. The right iliac fossa was occupied by a large tender tumour. The case did well, the bowels being relieved on the tenth day. There has been no return of the inflammatory mischief.

The symptoms may begin in a most indefinite manner and run a very slow course, in such cases being mostly gastric in character and liable to be treated as such.

[Dr. Hood here gave clinical descriptions of several other cases. He also quoted from Dr. Hawkins's monograph on Diseases of the Vermiform Appendix, and remarked that peritonitis occurring in connexion with the uterine appendages may sometimes create difficulties in the diagnosis. He continued:]

In the course of the last fifty years the treatment of these local inflammations occurring within the abdomen has passed through three stages. During the first period the main treatment was that of opium combined with calomel. Gradually the calomel was omitted from the prescription and treatment remained with opium alone. During later years opium with many has been dreaded, and early operation has taken its place. For my own part I attach the utmost importance to the making of an early diagnosis and to the early use of opium; I scrupulously avoid all aperient remedies.

The cases which have been under my own care include twelve private patients and twenty-three in hospital, all of whom, with the one exception above alluded to, made a good recovery, and in no instance was there suppuration. The cases seen in private have remained under observation and have been free from any form of abdominal discomfort. Hospital cases do not afford evidence of the good results which follow a simple medical treatment, in consequence of the fact that a large proportion of them do not apply until long after the commencement of their symptoms. My patients, on the contrary, with scarcely an exception, came under treatment at a very early stage of illness, and are of value as showing the results of a purely medical treatment. Practically a relapse is not of dangerous omen. Among my private cases in which the subsequent history has been known to me there were three instances of relapse. One was a child who sixteen years ago had two attacks within the same year and has had no return. The second was a man who suffered from a very severe form in 1879 and in 1881 had another, but since that date has had no return or any form of abdominal discomfort. The third was a young man who during 1888–9 had five attacks, in 1890 passed through typhoid fever and since the last attack of appendicitis has had no trouble of any kind referable to the abdomen. These cases were all treated with opium. The patient should be confined to bed and kept absolutely to slop diet—in fact, treated on the same lines as if suffering from typhoid fever. He should have hot applications to the abdomen, and from first to last should be rigorously kept from any form of aperient remedy. I have never seen any harm ensue from the bowels being confined for from seven to double that number of days. My plan has been to wait till the fall of temperature and then when scybalous masses are to be felt in the left iliac fossa to give a simple soap-and-water enema. Opium should be given from the first moment that diagnosis is possible. I prefer to administer it either in its solid form or as Dover's powder, the amount varying with the exigencies of the case, and I think that one is more likely to err from giving too little than from giving too much. In an ordinary case I give half a grain every four or six hours, and I have never seen harm ensue. It soothes the nervous system, renders the restraint of bed more endurable, relieves the pain which if untreated is often very great, promotes physiological rest of the part affected, and, in my opinion, promotes repair and restoration of the inflamed tissue. When I first commenced practice I used to combine belladonna with the opium, but soon gave up the use of the former drug, as I could find no material advantage in the combination and it had the disadvantage of making the throat dry and parched.

CASES OF SURGICAL TUBERCULOSIS TREATED BY KOCH'S NEW TUBERCULIN.

BY FREDERIC EVE, F.R.C.S. ENG.,
SURGEON TO THE LONDON HOSPITAL AND TO THE EVELINA HOSPITAL FOR SICK CHILDREN.

THE following eight cases are examples of surgical tuberculosis under my care at the Evelina Hospital in which the treatment by Koch's new tuberculin[1] (tuberculin R) has been completed, or nearly so. The first three cases of tuberculous disease of joints without sinuses or evidence of softening of caseous material show the only favourable results. Cases 2 and 3 were examples of early tuberculosis of the elbow and hip respectively. Of these it may fairly be said that the same results might have been anticipated from "surgical rest" and improved diet &c. In Case 1—a patient with relapsing tuberculosis of the knee of four years' duration—it seems probable that the remedy exercised a favourable influence. Case 5 was an instance of tuberculous peritonitis with ascites which was treated immediately after admission by laparotomy. During the administration of the tuberculin there was no re-accumulation of the fluid, but the child continuously lost weight. It was necessary to give the tuberculin very slowly and gradually owing to the weakly condition of the child and to avoid pyrexia; so that at the date of writing the treatment is only just completed. The remaining four cases were all examples of tuberculosis with sinuses. These, with one possible exception, were absolutely uninfluenced by treatment. The sinuses did not heal, and in three instances operation was ultimately required. Case 7, that of a child with tuberculous teno-synovitis of the dorsum of the hand, seems clearly to show that no immunity to tuberculosis was established by the treatment. The tuberculous material had become caseous and broken down with sinus formation, but was not, in the ordinary acceptance of the term, septic. After the conclusion of the tuberculin course all the tuberculous material was freely and carefully removed by operation, no bone disease being found. The wound healed by first intention, but two or three weeks later recrudescence occurred in the scar and subjacent tissues. The exception mentioned above was a patient with tuberculous epididymitis. A sinus remained after the opening of an abscess at the London Hospital just previously to admission to the Evelina Hospital. The sinus healed during the administration of tuberculin.

My own personal impressions[2] of the results of the new remedy may be summed up as follows. Some slight although no markedly favourable influence may be exerted in cases of early tuberculosis of joints or in those in which no evidence of softening of caseous material exists. But the effect where caseous material has broken down, and especially if the disease has become septic, is negative. The subsequent course of the cases described below will be carefully watched.

It cannot be said that the new remedy is altogether free from the drawbacks possessed by the old tuberculin of producing pyrexia and constitutional disturbance. In nearly

[1] Professor Koch's original article announcing the remedy appeared in the Deutsche Medicinische Wochenschrift, April 1st, 1897.

[2] My experience is not confined to the cases here recorded, but I have watched several other cases in which the treatment has not been completed and some under the care of my colleagues in which the course was completed.

Digitized by Google

every case a considerable rise of temperature occurred after one or two milligramme doses had been reached, and sometimes before. After this the duplication of successive doses, recommended by Koch, had to be given up for a more gradual increase. The pyrexia in some cases was very great, amounting to a rise of 7° F. Other unpleasant symptoms follow the administration of larger doses, such as vomiting, malaise, headache, and prostration. No local reaction was observed. In several instances abscesses formed at the seat of injection, although strict antiseptic precautions were enjoined. The number of these may in a measure be explained by the fact that during the progress of the trial we had several changes of resident officers. I am much indebted to our registrar, Dr. O. K. Williamson, for the following abstract of the notes of the cases; also to Miss Getz for the great help she afforded us in the administration of the remedy.

CASE 1. *Tuberculosis of the knee-joint.*—A girl, aged seven and a half years, was admitted to hospital on May 15th for a tuberculous knee. It was stated that the left knee became swollen and painful after a fall four years previously. Since then the swelling had increased. About a year before admission the knee became bent; it was straightened at the Dover Hospital and the limb was put in plaster-of-Paris. There were marked wasting of the left leg and swelling of the knee. The synovial membrane generally was much thickened and pulpy. Movements were extremely limited, but there was no displacement of the bones. On May 16th tuberculin ($\frac{1}{10}$ milligramme) was injected. Sixteen doses in all were injected. The dose was doubled each time until 16 milligrammes was the amount reached; after this the dose administered was always 20 milligrammes. The injections were given at intervals of two days until ½ milligramme was the amount reached. The intervals were then increased. Two doses of 20 milligrammes were injected. Sixty-four days was the period of time over which the injections were continued. As the result of the injections there was no local reaction. No marked rise of temperature took place until the dose of tuberculin had reached 4 milligrammes. The temperature on the evening after injection rose to 102° F. (a rise of nearly three degrees). The day after the injection of 8 milligrammes the temperature rose to 101·2° (two degrees rise). The day when 16 milligrammes were injected the temperature rose to 103·2° (from normal). The day after the first injection of 20 milligrammes the temperature rose to 101·2°, and on the day of the second injection the temperature rose to 101° (two degrees rise). After the injection of 16 milligrammes the child was very sick once. After the first injection of 20 milligrammes the child vomited several times, the face was pale, and she complained of headache; after the second injection of 20 milligrammes she was again sick and the face was very pale. On May 17th the knee was put up in a Macintyre's splint, in which it remained until June 25th. On June 24th the knee measured above the patella 8⅞ in. in circumference. On July 30th the measurement was found to be 8⅝ in. There was no apparent thickening of the synovial membrane, except slight fulness at the lower part of the patella on each side. The patella was found to be fixed, there was no movement in the joint, and no pain on percussion or palpation. The child was sent to a convalescent home wearing a moulded leather splint.

Remarks.—In this case the disease was well established, being of four years' duration, but no softening had taken place. The improvement was undoubted, but lapse of time must show if a permanent cure has been obtained. It is impossible to estimate in what measure respectively the improvement was due to rest, abundant diet, and nursing for seventy-six days, or to the tuberculin. Seeing that the disease was of such duration and that the joint had been treated at a seaside hospital I should be inclined to ascribe a large share of credit to the injections.

CASE 2. *Tuberculous disease of the elbow.*—A girl, aged four years, was admitted on April 21st for tuberculous disease of the elbow joint (right). About September, 1896, the mother observed after the child had had a fall that she could not straighten her arm and that the elbow was swollen. There was very little movement in the joint; it could not be extended to more than 120° or flexed beyond a right angle; rotation also was very much limited. The joint felt generally thickened. There was a distinct pulpy swelling in the neighbourhood of the radial articulation. An angular splint was applied. The child was healthy in appearance and well nourished. On May 8th $\frac{1}{10}$ milligramme of tuberculin was injected. Eighteen doses in all were administered. The dose was doubled until 15 milligrammes were reached; four doses of 20 milligrammes were then successively given. The interval between successive doses was two days until 2 milligrammes were reached. There were then intervals of four days and three days until 8 milligrammes were reached. The intervals after this varied from eight to eleven days. Seventy-two days was the period of time over which the injections were given. As the result of the injections there was no marked rise of temperature until 15 milligrammes were injected. After this there was a rise on the same evening to 102° F. (about four degrees). After the first injection of 20 milligrammes there was similarly a rise of temperature to 101·2° (from 97°). A rise occurred after the second injection of 20 milligrammes to 102° from 97 4°; and after the third injection there was an almost exactly similar rise of temperature. The day after the last injection there was a rise to 100 6° from normal. After the second injection of 20 milligrammes an abscess was observed at the seat of injection on the left side of the abdomen. The patient had been fretful in the night and had vomited once. After the third injection she had profuse sweats over the head and face. These were the only effects observed. On May 27th the circumference of the elbow taken round the groove on the front of the elbow and over the point of the olecranon with the elbow at right angles was 6¾ in. On Aug. 6th the circumference was found to be 6⅝ in., and the pulpy swelling had disappeared. The loss of mobility remained practically the same, but there was neither the slightest pain on movement nor tenderness. The child's general condition on leaving the hospital appeared to be thoroughly sound; she was very fat. The arm was put up in plaster bandages. The progress of this case of early tuberculous disease was in every way satisfactory.

CASE 3. *Hip-joint disease.*—A boy, aged five years, was admitted with hip disease (left) on April 21st. The boy limped and complained of pain on walking. The limping was noticed a week after he fell from a seat in March last. There was some fulness in the left groin, and very little movement in the joint could be obtained. The boy was well nourished. On April 24th weight extension (4 lb.) was applied; on May 13th this was stopped and a double Thomas's splint was applied. On May 7th $\frac{1}{100}$ milligramme was injected. Eighteen doses in all were injected. The second dose was $\frac{1}{50}$ milligramme; the dose was then doubled each time until 15 milligrammes were reached; after this four successive doses of 20 milligrammes were administered. Seventy-three days was the period of time over which the injections were continued. The interval between successive doses was usually two days until 2 milligrammes was the amount reached. The intervals after this were in order four, three, eight, eight, eight, eleven, and ten days. As the result of the injections there was no marked rise of temperature until ¼ milligramme was injected. On the evening after this there was a rise of temperature to 100·4° F. (from 97°). The next marked rise of temperature was after the injection of 2 milligrammes. The day after this the temperature rose to 100° (from normal). Again, the day after the injection of 4 milligrammes the temperature rose to 99·8° (from 97°). After the injection of 8 milligrammes there was a rise next morning to 103 8° (from 97°); and after the injection of 15 milligrammes there was a rise to 105·6° (from 97·8°). After the first injection of 20 milligrammes there was a rise of temperature to 103·8° (from 96·4°), after the second injection a rise from 97° to 103°, after the third injection a rise from 97° to 103·6°, and after the fourth injection a rise from normal to 103·2°. After the injection of 15 milligrammes he was sick several times, slept very little, the face and hands were occasionally cold, and he had profuse general sweats. After the first injection of 20 milligrammes he vomited a few times; after the second injection he vomited three times, his face was pale and he complained of pain in the abdomen; after the third injection he had similar symptoms, and after the fourth injection he was once sick. On July 9th there was still some fulness in the left groin. The joint admitted of a certain amount of movement without pain, especially flexion. The thigh could be flexed to an angle of 40° with the horizontal. The boy left the hospital on a double Thomas's splint.

Remarks.—In this case it may be said that the same amount of improvement would have followed "rest" and general

Digitized by Google

treatment in a large proportion of cases of disease of the hip-joint.

CASE 4. *Caries of the tarsus.*—A girl, aged six years, was admitted to hospital on Feb. 13th for a sinus discharging thin serous pus on the anterior surface of the left foot. Two and a half years ago the child went into the Forest Gate Infirmary with wasting. She was discharged in August, 1896, apparently well, with the exception of a discharging sore on the left foot. Since Christmas wasting and night sweats had been present. The sinus led to carious bone. The dorsum was swollen and pulpy. On March 12th the scaphoid, cuneiform bones, and cuboid were removed by two incisions on the outer and inner sides of the dorsum of the foot respectively. The bones of the foot were then brought together by means of deep catgut sutures, the wound was dressed with cyanide gauze, and the foot was placed in plaster splints. On admission there was also a large indurated swelling in the right lumbar region with a lateral curvature to the right. On April 6th, of the two granulating wounds on the dorsum and external surface of the foot respectively the outer one had healed and the inner had not. On the 28th a small abscess in the groin (right) was opened. At this date the wound in the foot was nearly healed, but one corner was rather inclined to break down. The child was thin and rather pale. On May 8th $\frac{1}{100}$ milligramme of tuberculin was injected. Eighteen doses in all were injected. The particulars with regard to the doses and the intervals between successive doses were precisely the same as in Case 6. As the result of the injections the temperature was not observed to rise until 1 milligramme had been injected. On the evening after this there was a rise from 97·4° to 101°F. On the day of injection of 8 milligrammes there was a rise from 97° to 101 4°. On the day of injection of 15 milligrammes there was a rise from normal to 104°. On the day of the first injection of 20 milligrammes there was a rise of temperature from normal to 103°; on the day of the second injection of 20 milligrammes there was a similar rise; on the day of the third injection of 20 milligrammes there was a rise of temperature from normal to 101 2°; and on the day of the last injection there was a rise of temperature from normal to 102·4°. After the injection of 15 milligrammes inflammation was observed at the seat of injection, she slept badly, complained of headache, and vomited several times. After the first injection of 20 milligrammes her face was pale and she vomited once. An abscess formed at the seat of injection. After the second injection of 20 milligrammes she vomited several times; after the third and fourth injections there was, however, no sickness. On July 2nd, after having had two injections of tuberculin of 20 milligrammes, the sinuses in the foot were scraped with a sharp spoon and some softened bone removed. The sinus in the right groin was opened and scraped. The edges of the wound were brought together with silkworm gut.

Remarks.—The local disease was apparently uninfluenced by the tuberculin. The child was sent to a convalescent home with a sinus still open on the dorsum of the foot.

CASE 5. *Tuberculous peritonitis (ascitic variety).*—A female infant, aged seventeen months, was admitted on May 14th. The abdomen was greatly distended, with bulging in the flanks, and very tense; a fluid thrill was easily obtained. The child was plump and looked healthy; her colour was good. On June 3rd laparotomy was performed. Much serous fluid was let out from the peritoneal cavity and the peritoneum was found to be studded with tubercles. The operation wound healed well. On June 8th $\frac{1}{100}$ milligramme tuberculin was injected. The dose was very gradually increased, the full 20 milligrammes not being reached until September. The child had lost 4 lb. 4 oz. since admission and looked pale. Distinct nodules were to be felt in the neighbourhood of the wound, but there was little if any reaccumulation of fluid. This patient was transferred to me for surgical treatment by my colleague, Dr. Willcocks.

CASE 6. *Tuberculous dactylitis.*—A girl, aged ten years, was admitted to hospital on April 24th for tuberculous dactylitis. There was thickening of the first phalanx of the ring finger of the left hand, the tissues over the thickened part were inflamed, and there was a large fungating ulcer on the posterior and ulnar surface of the finger. The patient's general condition was good. The forearm and hand were put up in an anterior splint. On May 8th $\frac{1}{100}$ milligramme of tuberculin was injected; eighteen doses in all were administered. The dose was doubled each time of injection until 16 milligrammes was the amount injected. The next dose was 20 milligrammes, and the dose thenceforward was kept at this. The injections were given at intervals of two days until the dose of 2 milligrammes was reached; there was a four days' interval between the injections of 2 and 4 milligrammes; three days between the injections of 4 and 8 milligrammes; seven days between the injections of 8 and 16 milligrammes; and nine days between the injections of 16 and 20 milligrammes. After this the intervals varied from eight to eleven days. The last dose was on July 19th. Seventy-two days was the period of time over which the injections were continued. Four doses of 20 milligrammes each were injected. The temperature did not rise until $\frac{1}{2}$ milligramme was injected. The same day it rose to 101° F. (from 98 4°). The day after 4 milligrammes were injected the temperature rose to 102·2°, after 8 milligrammes to 102°, whilst the same day that 16 milligrammes were injected it rose to 104·6°. On the day of the first injection of 20 milligrammes the temperature rose to 103 8°, on the day of the second injection of 20 milligrammes to 105·6°, on the night after the third injection to 103°, and on the day of the fourth injection to 102 4°. After the injection of 8 milligrammes an abscess was observed at the seat of injection, with inflammation around it. After the injection of 16 milligrammes headache was observed coincidently with the rise of temperature. There were also redness and great tenderness at the seat of injection, and the patient was sick afterwards. After the first injection of 20 milligrammes the hands and face were observed to be cold coincidently with the rise of temperature. After the second injection she complained of headache, the face was very pale, and she was sick once, coincidently with a rise of temperature. On July 30th an operation was performed. An incision was made over the dorsum of the first phalanx, and a sinus was found leading into the interior of the shaft of the bone. Neither joint was affected. On the external surface of the ligaments of the first interphalangeal joint some recent tuberculous granulation tissue was found. The interior of the thickened shaft of the first phalanx was filled with diffluent caseous material. The operation wound healed *per primam*.

Remarks.—Soon after the commencement of the injections the ulcer partially healed and the swelling of the soft parts of the finger diminished. This may have been due to careful antiseptic dressing, rest, and improved diet. Subsequently the condition of the finger became stationary.

CASE 7. *Tuberculous teno-synovitis.*—A boy, aged eight years, was admitted on June 1st for tuberculous disease of the dorsum of the hand, which had been affected on and off for three or four years, but had become worse lately. There was considerable thickening over the fourth metacarpal bone of the left hand, and some ulceration of the skin. The first phalanx of the ring finger was also considerably thickened, and there was a discharging sinus in the palm. The boy was delicate in appearance and decidedly thin. A palmar splint was applied. On June 4th $\frac{1}{100}$ milligramme of tuberculin was injected. Fourteen doses in all were administered, the dose being doubled each time until 16 milligrammes were reached. The injections were made at intervals of two days until $\frac{1}{10}$ milligramme was reached. Then intervals of from three to eleven days were allowed to intervene until 2 milligrammes were injected; then intervals of two days until 16 milligrammes was the amount reached. This was arrived at on July 31st. Fifty-seven days was the period of time over which the injections were continued. As the result of the injection a rise of temperature to 103° F. was observed the day after $\frac{1}{125}$ milligramme was injected (nearly three degrees rise). The day of injection of $\frac{1}{10}$ milligramme the temperature rose to 102° (about three degrees). The next occurrence of marked rise of temperature was on the day after $\frac{1}{8}$ milligramme was injected, when there was a rise to 102 2° (about four degrees). The day after injection of $\frac{1}{2}$ milligramme there was a rise of temperature to 102·8° (about five degrees), the day after injection of 1 milligramme there was a rise of about four degrees, after 2 milligrammes to 102·2° (about three degrees), the next important rise being after 16 milligrammes to 104° (from normal). No other effects were observed. On July 30th the swelling on the dorsum of the hand was incised and found to contain diffluent caseous material connected with tendon sheaths but not with bone. A communication existed with the ulcer on the palmar surface.

Remarks.—Primary union took place; but from two to

Digitized by Google

three weeks later the scar became tuberculous and broke down. As the result of treatment the swelling rather increased and the skin over the tuberculous granulation tissue broke down at several points. Two sinuses existed when the child came under observation, but there was practically no suppuration.

CASE 8. *Tuberculous epididymitis.*—A boy, aged ten years, was admitted to hospital with tuberculosis of the epididymis on June 7th. There was a sinus on the left side of the scrotum, the skin around which was adherent to the left testicle. The sinus discharged serous fluid. Marked thickening of the epididymis existed, but the vas was normal. The boy, although thin, looked healthy. Previously to admission at the Evelina Hospital an abscess connected with the left testicle was incised at the London Hospital and the sinus remained. On June 8th $\frac{1}{500}$ milligramme of tuberculin was injected. Nine doses in all were administered. The dose was doubled on each occasion the largest dose reached being $\frac{1}{2}$ milligramme. Forty-three days was the period of time over which the injections were continued. As the result of the injection the first marked rise of temperature was on the day after the injection of $\frac{1}{125}$ milligramme, when it rose from normal to 100·8° F., the next rise being after the injection of $\frac{1}{30}$ milligramme, when it rose from normal to 100·6°. The remaining injections caused apparently no rise of temperature. After the injection of $\frac{1}{30}$ milligramme redness and tenderness were observed at the seat of injection. The sinus healed and the patient was then discharged.

Harley-street, W.

A CASE OF ULCERATIVE ENDOCARDITIS SUCCESSFULLY TREATED WITH ANTI-STREPTOCOCCIC SERUM.

BY J. W. WASHBOURN, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE LONDON FEVER HOSPITAL; ASSISTANT PHYSICIAN TO GUY'S HOSPITAL, ETC.

A FEMALE, aged twenty years, was admitted into Guy's Hospital under my care on Jan. 26th, 1897, complaining of pains in the joints and general malaise. Her father was stated to have died from phthisis and heart disease; otherwise the family history was good. Her occupation was that of a ward maid. She had hitherto enjoyed good health, never having been laid up. The present illness began four days previously with pains in the joints, headache, and shivering. On admission she was found to be a well-nourished, healthy looking young woman. She complained of headache and of pains in the knee and thigh. The heart, lungs, and urine were quite normal and there was no swelling or other evidence of disease in any of the joints. The temperature was 100·6° F., the respirations were 24, and the pulse was 104. On Jan. 27th the temperature, which was taken every four hours throughout the illness, became normal, and remained so for three days. I hoped that she was convalescent, having considered the attack to be one of influenza, but on Jan. 30th the temperature again rose, and from this date until March 16th she suffered from irregular pyrexia. With the exception of three days the temperature rose for a few hours every day to 102°, 103°, or even 105°, and there were frequent rigors and perspirations. During the whole of this period she was carefully examined every day. The heart, lungs, urine, ears, eyes, vagina, and rectum appeared to be perfectly normal. The pulse varied with the temperature, when the latter was normal the pulse-rate was 80 or 90 per minute. The blood shewed slight leucocytosis and slight decrease in hæmoglobin. Some carious teeth were removed, but there was no sign of inflammation in the alveoli. She suffered a good deal from constipation, requiring the frequent use of aperients. In spite of treatment with quinine and salicylate of soda she gradually became worse; the rigors were more frequent, she lost her appetite, and became pale and thin. On March 16th a distinct diastolic bruit developed on the left side of the sternum, its maximum point of intensity being the third intercostal space. It was then quite clear that the pulmonary valve was affected and that the patient was suffering from ulcerative endocarditis. On March 24th anti-streptococcic serum was first injected, and, with the exception of three days, the injections were continued daily until May 25th. The serum employed was that of the British Institute of Preventive Medicine, and it was given in doses of 20 c.c. until the last two weeks of treatment, when the dose was gradually diminished. The treatment lasted altogether nine weeks, during which time 1030 c.c. serum were injected in fifty-nine doses. The effect of the treatment is best shown by the chart, which is, unfortunately, too long for publication. During the first fortnight of treatment there were only two slight rigors, but the pyrexia persisted. On April 6th, a fortnight after the commencement of the treatment, the temperature became normal and remained so until the 26th. By this time the patient was so well that the injections were ordered to be given every other day instead of daily. The effect of this alteration in treatment was that the temperature rose on the 28th to 99.6°, on the 30th to 100·4°, and on May 3rd to 100·6°. The injections were again given daily, with the result that the temperature fell to normal on May 6th, and continued so until July 19th, when the patient was discharged from the hospital. On May 13th the dose of serum had been reduced to 10 c.c., and on the 22nd to 5 c.c. On the 25th the injections were omitted. The general condition of the patient began to improve five or six days after the commencement of the injections, and three weeks later she was to all appearances quite well. On leaving the hospital on July 19th the diastolic bruit in the pulmonary region was still present. Neither now nor on any previous occasion did the heart show any sign of enlargement. The only inconveniences noticed from the frequent injections of the serum were slight pain at the site of injection and an urticarial rash, which appeared on April 1st and lasted a few days. After leaving the hospital the patient went to a convalescent home. She was seen a month later, and appeared to be in perfect health, but the bruit still persisted.

Remarks.—Cases of ulcerative endocarditis treated with serum have been recorded in THE LANCET by Dr. Harrington Sainsbury,[1] Dr. A. E. W. Fox,[2] and Dr. Margaret Pearse.[3] The above case appears to be more definite in its nature and in the result of the treatment than any of these cases. The patient came under observation a few days after the commencement of the illness. During the first seven weeks she suffered from an ill-defined septicæmia without any local manifestation of disease, and there was at no time distinct evidence of the site of entrance of the contagion. Up to the time when the serum was first injected she was progressively losing ground; and a few days before the commencement of the injection, the pulmonary valve became affected. The result of the treatment was most striking and I am quite satisfied that it saved the patient's life. The pyrexia ceased after the first fortnight of treatment, and the general condition very quickly improved. At the end of five weeks the patient seemed so well that the injections were given every other day instead of daily. As a result of this alteration the temperature began to rise, but again subsided when the injections were given daily. During the last fortnight of the treatment the quantity of serum injected daily was gradually diminished, and after the final omission of the injections no further rise of temperature occurred. The patient with the exception of pulmonary regurgitation, was perfectly well on leaving the hospital and was seeking a situation a month later. The large amount of serum used is worthy of record. The treatment lasted nine weeks, during which time 1030 c.c. serum were injected in fifty-nine doses. The only ill-effect was a transient rash. Throughout the case the cardiac symptoms remained in the background, the infective process being the most prominent feature. Such a case as this is the most favourable for serum treatment. In so many cases of ulcerative endocarditis the infective process is engrafted upon old cardiac trouble, and even if the serum controls the septicæmia, the patient has still to contend against cardiac inefficiency. The antistreptococcic serum was used because it was thought that the case was most probably one of streptococcic infection, although we possessed no bacteriological evidence of the presence of streptococci in the blood.

PARTIAL AND COMPLETE DISLOCATION OF THE SEMILUNAR CARTILAGE OF THE KNEE; OPERATION ON SIX CASES.

BY ARTHUR E. BARKER, F.R.C.S. ENG. AND IREL.,
PROFESSOR OF THE PRINCIPLES AND PRACTICE OF SURGERY, AND PROFESSOR OF CLINICAL SURGERY AT UNIVERSITY COLLEGE, AND SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

THE mechanism of the knee-joint has always appeared to me to be one of the most interesting problems in anatomy, but one at the same time far from being satisfactorily explained. To call the knee simply a hinge-joint is quite an inadequate description, though true up to a certain point. It is a hinge undoubtedly, but a hinge with far more complex movements and limitations of movement than are suggested in the name. The difficulties in explaining the details of movement in the joint will probably never be entirely cleared up by anatomical studies on the dead body. So many changes take place after death in the tone of the muscles and in the tension of the ligaments when the capsule has been more or less completely removed that the normal movements within the joint are probably rarely or ever seen post mortem. But in the living subject the case is otherwise, and it is possible to examine many points which after death would probably be considerably altered.

Having operated on the knee-joint very fully in a great number of cases its internal anatomy *in vivo* is very familiar to me. And having lately opened it on six different occasions for the study and treatment of the very distressing condition due to displacement of a semilunar cartilage, I should like to place on record exactly what has been found as a small contribution to the anatomy of the joint as well as its pathology. The subject deserves a much wider study than would be possible in a paper such as the present.

The clinical history of these cases is the first factor in throwing light upon the mode of production of the injury and the movements of the semilunar cartilage. In the first place, in all the many cases which I have seen, besides those I have operated on, the displacement has been progressive—that is, it has been very slight at first and has gradually increased until complete. In the next it has, I believe, invariably been the internal meniscus which has been displaced. Out of many dozens of these cases which I have seen I cannot recall a single one in which the external cartilage was dislocated. And in all those I have operated on it was clearly seen that the internal was the part out of place. Again, by far the largest number of cases have been among males in my experience, and I have never yet been called upon to operate on a female. The condition has been usually seen among young and vigorous men, my oldest patient being forty-four years of age. This was the only case in which a severe injury appeared to have been the commencement of the lesion. Here (Case 2) the patient had severely twisted his knee by a fall out of a truck. But the ultimate dislocation probably did not take place upon this occasion, but the injury only prepared the way. In every case the history of the initial lesion was almost always identically the same. The patients were either walking quietly on the level, or, if we include cases not operated on, were slowly sauntering upstairs, getting out of a bath, mounting or dismounting from a bicycle or horse, and a slight catch was felt on the inner side of the joint. In all, the displacement occurred while the knee was very slightly flexed, and usually while there was very little muscular effort being put out. In one case, it is true, the patient was playing football when his knee "gave." Then there was a history in all cases of recurrent attacks like the first at ever-shortening intervals and each time with more severe symptoms. In some cases where the descriptions were particularly accurate the patients noted the "slipping out" to have occurred while the limb was not only slightly flexed, but at the same time the leg was rotated outwards on the thigh. This I believe to be the rule. In the less marked cases the first and second attacks left but little ill effects behind and extension was as good as before, but usually much swelling due to synovitis followed subsequent attacks and ultimately remained for a long time. In the severe cases verified later by operation there was a history of a very sharp attack after the first two or three milder ones, and after this there was inability to extend the knee fully, and usually permanent effusion. In none could any foreign body be felt in the knee, and any *palpable* evidence of the absence of the meniscus from its usual place was not discoverable by the finger. In the examination of the knee and remedy of the displacement the same operation was performed in every case.

With the limb extended a curved incision reaching from the inner border of the ligamentum patellæ to the anterior edge of the lateral ligament was first made. The ends of this incision in all cases corresponded to a line a little above the level of the upper rim of the tibia; the convexity of the flap reached down for about one inch on the head of the latter. The periosteum was raised with the flap, which also, of course, contained the capsule besides, but the fibres of the latter were left intact in their relation to the periosteum. This I believe to be most important for the subsequent strength of the joint. When this flap was raised the cartilaginous rim of the articular facet was in every case seen to be divested of its covering semilunar cartilage, and except in Cases 1 and 4 the latter could not be seen at all with the limb in the extended position. In these two cases the meniscus was seen to be detached only in the outer part of its periphery from the capsule, and to have slipped in more or less between the bones. But in neither case had it disappeared from view. But in the other four cases when the joint was opened as above no semilunar cartilage was to be seen at all with the knee extended. The flap turned up showed where it had been detached, but the meniscus itself had disappeared. But when the joint was flexed to about a right angle it became possible to see the loosened mass lying in the inter-condyloid notch against the crucial ligaments. In three out of the four in which it was found in this condition of complete inward dislocation it was only held by its extreme ends; in the last case there was still a trace of its capsular union anteriorly. In all these cases of entire dislocation inwards the reduction was effected by a pull forwards with a sharp hook, the knee being strongly flexed. And it was remarkable how strong the traction required to be in order to restore the meniscus to its proper position. It always came out with a slip suddenly, and the knee could then be fully extended. But quite as remarkable as the need of strong traction to bring it out was the tendency it had to return to the inter-condyloid notch when the knee was slightly flexed. It appeared to be dragged in suddenly during flexion, and if the hook were left loose it would carry it with it. This was so remarkable that I demonstrated it over and over again in more than one case to those present. It was easy to see in all these movements of the knee that in those cases in which the meniscus was rolled up in the middle of the joint nothing short of traction with a hook could have brought it into the normal position; but in Cases 1 and 4, where only part of the peripheral attachment had given way, replacement in slight flexion was quite easy.

From a study of these cases I have satisfied myself, therefore, that where I have been successful in reducing a semilunar cartilage by manipulation without opening the joint the dislocation must have been incomplete, and, indeed, comparatively trifling, only a part of the capsular attachment having been torn, or, perhaps, only stretched. The other cases (2, 3, 5, and 6) all showed that no manipulation or movement of the joint could ever have restored the meniscus to its original position. These six cases operated on showed the derangement of the joint in every stage when taken in the following order—1, 4, 6, 3, 5, and 2. Case 1 showed detachment of part of the periphery and very moderate displacement. Case 4 showed a wider separation of the meniscus from the capsule and greater displacement; the other cases all showed complete dislocation into the inter-condyloid notch. In Case 6 there was still, however, a trace of the capsular attachment left anteriorly, but in the rest the latter had quite given way and the cartilages were only held by their ends. But in Case 2, not only was this the case, but the meniscus, from long dislocation, had altered materially in shape and appeared corrugated so as to accommodate itself to its new position. I find, too, in the notes that it appeared to have contracted adhesion in its new position; and perhaps this was the case, but I suspect that the difficulty in drawing it out and in keeping it fixed during suture of its edge was more due to its being crumpled and perhaps shrunken somewhat. This fact of crumpling and shrinkage probably explains, too, the longer time taken by this patient to recover the free use of his knee than in any of the others. It will also doubtless explain the great amount

Digitized by Google

of effusion into the joint which took place in this case after operation, and which required aspiration of the synovium two or three times within the first few weeks. And even now, though the man is running about quite well at his work, and very cheerful about his leg, there is still some slight stiffness in moving the joint. Of course, this was the oldest patient of the series, and the dislocation was of longer standing than in the other cases, except Case 5, factors which no doubt told on convalescence and completeness of recovery. In the other cases of younger men in whom the condition had not, with the exception of Case 5, lasted so long, the recovery was more perfect, and the reaction in the joint after operation practically *nil*. In Case 5 there was considerable reaction and slow recovery of power. It happens that within the last few weeks I have heard from several sources of Case 1. This young officer is now in India and taking part in all the exercises of his profession and in athletics as if his knee had never been injured. Case 3 has been lost sight of, but the last note in the hospital record was, "Joint looks quite normal." Case 4 I have seen and heard of several times since operation. He is rejoicing in complete restoration of the joint. Case 5 is that of a young naval officer who is back at his work and able for it. There was a considerable swelling on the inner side of the joint when I last saw him nine months after operation and still some stiffness. He was then still nervous about using the limb to its fullest extent, but unnecessarily so.[1] In this case there was great displacement, and the condition had lasted for a considerable time, three years probably, as in Case 2. The consequence was much alteration in the meniscus while displaced. Case 6 is still under observation. His convalescence has been absolutely uneventful; there was no reaction at all in the joint after operation, and he is beginning free movement. In this case, though there was complete dislocation, I expect a more than usually good result for the operation was performed within three days of that attack which resulted in dislocation.[2]

It was very interesting to note in all these instances that the patients' statements that in many cases the joint "went out" during slight flexion and eversion were confirmed by observation of the movements of the semilunar cartilage during flexion and extension *in vivo*. On looking into the joint after reducing the meniscus the latter was always seen to move inwards during flexion. This was not merely a simple slipping inwards, but a dragging inwards, which could be felt when a hook was inserted in the meniscus itself; and in the cases in which the detachment was marked the cartilage was plainly dragged into the middle of the joint with the hook and with considerable force. Slight flexion began the movement, which seemed to increase the more the knee was bent, until finally the meniscus slipped over the convexity of the femur and got between the condyles and remained there.

Through the kindness of my colleague, Professor Thane, I have been able more than once lately to examine a number of variously dissected knee-joints, and in these, too, the movement of the cartilage backwards and inwards during flexion can be seen to a certain extent, but far less marked than in the living knee. But the mechanism of the movement is far from clear either in the dead or living joint. What *appears* to take place is this. In the first place during flexion the point of contact between the femur and tibia appears to shift backwards a little. This in itself would relieve the pressure on the anterior curve of the meniscus and push the posterior curve backwards. But in addition it would incline the internal lateral ligament somewhat backwards, and in this way drag the semilunar cartilage back through its attachment to the lateral ligament. Apparently one at least of the functions of the posterior crucial ligament is to prevent the femur from slipping too far backwards, for it is rendered tense in flexion. Whether this explanation of the causes of the displacement of the meniscus be correct or no the fact remains that during flexion in the living joint it can be seen to slip backwards. The actual dislocation, of course, is due to the nipping of its edge when the limb is extending, which fixes it between the two bones and prevents it travelling forwards, while the capsule, being rendered tense by extension, is torn away from it more and more until there is nothing to prevent it slipping into the middle of the joint. Whether when it has once been completely dislocated thus it ever returns to its normal position is, I think, doubtful. I imagine that in those cases in which it has been supposed to do so the dislocation has not been completely into the centre of the joint, but has been a partial nipping. The appearance of the meniscus in those cases in which I have seen it lying against the crucial ligaments was certainly such that its return without considerable traction appeared an impossibility. It was puckered, thickened, and apparently shrunken.

From all this it would appear that given a knee-joint in which this derangement has taken place incontestably and has been repeated an operation ought to be performed without delay so as to prevent the complete dislocation from taking place. If the latter has occurred there is the more reason for immediate interference before the semilunar cartilage becomes altered in shape and texture. In such cases the manipulations during operation must be more severe and the reaction thereafter more decided, while a complete *restitutio ad integrum* is much less likely owing to the changes in the cartilage and other structures of the joint. If the operation is not performed reasonably early there is a danger of the displaced cartilage being so seriously altered in texture and shape that it cannot be restored to position, and nothing remains but to excise it completely and leave the joint without an internal meniscus.

The following six consecutive cases form an interesting group.

CASE 1.—The patient, aged twenty-four years, while playing rackets in April, 1895, slipped, "and felt something go in his right knee." He had sharp pain, and the joint swelled up and he could not bend it. This swelling lasted a month, when he thought the cartilage must have gone back into position, for the swelling suddenly went down; but soon after he had a return of symptoms. He was then put in splints. Recovery again took place, but three weeks later the same "slip" occurred. He was then invalided. Since then he had put the knee out five times, and on each occasion swelling has followed. The operation was performed on Oct. 3rd, 1895, in the same manner as in the other cases. The cartilage was only partially separated from the capsule and was drawn out with a hook and stitched to the posterior surface of the flap raised. Three silk stitches were used, which at first tended to cut out of the cartilage. The wound was closed in the way described and dressed with salicylic wool. There was no drainage. Primary union took place with very slight synovitis.

CASE 2.—A man, aged forty-four years, had been always healthy and with a good family history. He strained his left knee a year previously in a fall from a truck. Three months later, while walking, he felt pain in the same knee, but after a few seconds he was able to put it straight again. Similar attacks had occurred every two or three weeks since. In October, 1895, he had a bad attack and was unable to straighten the limb for about three weeks, the joint at the same time being very much swollen. He was unable to walk for six weeks and three days; after he began to go about the knee locked as before and he was off work for five weeks. The patient was a robust and finely developed man; there was no enlargement of the joint and nothing otherwise abnormal about the knee to be felt. He was able to walk except when the cartilage was displaced. The operation was performed on Feb. 20th, 1896, in the same manner as the other cases. When the joint was opened the semilunar cartilage was found to be torn away from the capsule all round and to be curled up against the crucial ligaments in the intercondyloid notch, where it had contracted adhesions. When it was drawn into its normal position by means of a blunt hook with the knee slightly flexed it could be retained there by full extension of the joint, but upon the slightest flexion it slipped back into the old position, dragging the hook with it with some force. Six fine silk sutures were inserted through its outer border, and it was stitched to the flap of the capsule and periosteum as in the other cases. This flap was then sutured *in situ*, and the wound was closed without drainage. There was a good deal of pain in the joint next day, but this soon passed off. The first dressing was on the sixth day, when all the wound but its two ends was found united *per primam*. There was a good deal of fluid in the joint. On the tenth day the wound was perfectly healed and the fluid, consisting of yellow serum, was aspirated. Four days later the joint was again aspirated, as the fluid had re-accumulated to the extent of three ounces. About this time there was mild lymphangitis with tenderness up the thigh and in the groin. The wound, however, remained perfectly quiet. There was throughout retention of urine requiring

[1] Since this was written I have heard by letter from this patient from the Red Sea. He is now quite well.

[2] Since writing the above I have seen this patient. His joint is perfectly normal in every way, and he is able for every kind of exercise.

Digitized by Google

the catheter. Either owing to the lymphangitis, or perhaps the retention, the temperature was raised for fifteen days, on one occasion to 102·2° F. It then fell, and convalescence was uninterrupted further. Under massage the swelling of the joint improved much before the patient was discharged on April 4th. I have since seen him several times. He is now at work and with a good knee. There is slight limitation of extreme flexion and a trace of swelling. Otherwise nothing is to be noticed, and he expresses much satisfaction with the result.

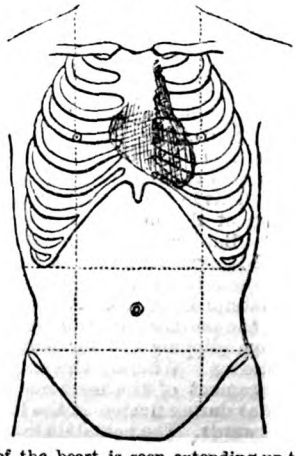
CASE 3.—A man, aged thirty-eight years, had always been healthy and had a good family history except that his father died from "consumption." In January, 1896, he felt the left knee "give" while walking quietly. After this the joint swelled and he used a liniment. At the end of a fortnight he could get about without any abnormal sensation in the joint except the "slipping of something" occasionally, but the swelling remained with pain and throbbing and an occasional crack for a time. When seen there was no pain, but the joint was somewhat enlarged with fluid. Flexion produced no pain. The operation was performed on May 1st, 1896, in the same manner as in the other cases. Here, too, the semilunar cartilage was found to have completely slipped into the inter-condyloid notch, from which it could only be drawn out into position by means of a hook and retained by full extension of the joint. When the latter was slightly flexed it at once suddenly slipped back to the crucial ligaments. It was fixed by four silk sutures *in situ*, and the wound was closed without drainage. There was much pain during the following night and little sleep. This lasted for a day or two, being most marked at night. On the sixth day the first dressing was changed and union *per primam* was found, the joint looking quite normal. Collodion and wool were applied. The skin stitches were removed on the ninth day, and the knee was massaged daily. He left the hospital on June 6th quite well. The temperature on the first and second days rose to 100·2° F., and then fell to practically normal. Convalescence was uninterrupted. I have not seen or heard of the patient since his discharge.

CASE 4.—A man, aged forty years, had always been healthy and very active. While playing football four months previously he felt his left knee give way under him while he was kicking the ball with his right foot. At the same moment he felt something slip in the joint, which was followed by great pain. He was compelled to rest for a month, and was then able to use the leg as before, but it was weak. A fortnight later he felt the same twist while bowling at cricket, but less severely than the first. Notwithstanding, in spite of keeping his bed for fourteen days, recovery was not so rapid and complete as before. A week before admission to University College Hospital, on June 23rd, 1896, exactly the same accident happened to his knee while leaning forward on a prop fixed in the ground. Since then he had kept his bed. On admission the knee was kept slightly flexed with a slight degree of rotation outwards. Flexion produced no pain. There was slight wasting of the thigh. The operation took place on July 2nd, 1896. The semilunar cartilage was only separated from the capsule at its posterior and inner aspect, and only slightly displaced inwards. Similar sutures and dressing to those in the other cases were used, and there was no drainage. The temperature rose gradually day by day to 101·2° F. on the seventh day, and then gradually fell to normal. Healing took place *per primam* except at one point, where one of the deep silk ligatures projected a little. The patient went home on July 31st. He returned to show himself some weeks later. He was walking well and was very cheerful about himself. One of the deep ligatures was seen projecting from a moist spot in the scar. This I removed. I have seen the patient since quite well and with a perfectly sound knee.

CASE 5.—A young naval officer had the usual history of several more or of less severe attacks in the right knee which had commenced three years before. The knee was slightly flexed and could not be extended fully, but there was not much pain and only trifling thickening round the joint. Nothing abnormal could be felt on the borders of the joint. On April 16th, 1896, I operated as before described and found the massive semilunar cartilage lying, bent and twisted, between the condyles. When drawn out with a hook it showed the greatest tendency to recoil to its old vicious position, and, in fact, did so when the hook was left to itself. This was so remarkable that I asked my friend, Dr. Dudley Buxton, who was giving chloroform, and who had seen my other cases, to come round from the patient's head and look at it. The meniscus was stitched in position, as in the other cases, and the wound closed without drainage. The wound healed *per primam*, but there was some effusion into the joint which absorbed slowly. When seen last Christmas there was still slight stiffness, but relief was otherwise complete. He is now abroad and quite well.

CASE 6.—A healthy young man, aged twenty-one years, first noticed a sharp click in his right knee while vaulting over a bar three years ago. There was pain at the same time, but this soon passed off. He experienced the same sensation shortly after. Finally, on May 2nd, 1897, two days before admission, while playing in a field and starting to run, his knee suddenly gave out, and he found he could not extend it easily or walk with any comfort. He was obliged to keep it somewhat flexed. On admission he complained of inability to extend the right knee, which was kept in a state of flexion, but could be moved in greater flexion without pain. There was no swelling of the joint, and nothing abnormal could be felt. On May 4th I operated precisely as in the other cases, and found the meniscus curled up in the inter-condyloid notch torn from its capsular attachments, except just at its anterior curve. It was reduced in flexion with a hook, and the rest of the operation was soon finished. There was absolutely no reaction in the joint, and when the superficial sutures were removed on the twelfth day primary union was complete.

Harley-street, W.



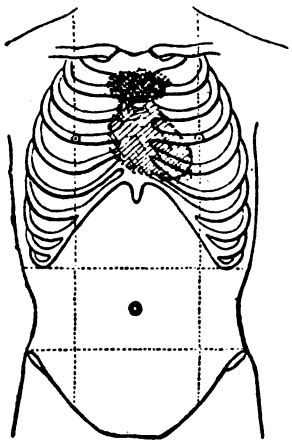
THE ROENTGEN RAYS IN MEDICAL DIAGNOSIS.

BY H. CAMPBELL THOMSON, M.D., M.R.C.P. LOND.,
MEDICAL REGISTRAR TO THE MIDDLESEX HOSPITAL.

THE following cases are of some interest in showing the value of the Roentgen rays in medical diagnosis. In all of them the fluorescent screen was used, as it is more certain and far less tedious than photography for making examinations of the chest. The diagrams show the appearances of the cases as seen upon the screen; the ribs and sternum, which in reality appear dark, have been left clear in the diagrams in order to avoid confusion.

CASE 1.—A man, aged forty-nine years, was admitted into the Middlesex Hospital complaining of paroxysmal attacks of pain in the chest which had occurred on and off for the past five years. On admission the physical signs were as follow: the apex beat of the heart was in the fifth interspace, but displaced a little outwards, so that it was in the vertical line of the nipple. The first sound was weak, but the second sound at the aortic base was loud and ringing in quality and was accompanied by a systolic murmur. The percussion note over the manubrium sterni was impaired, and some slight pulsation could also be felt over this area. The voice was rather hoarse occasionally, but a laryngeal examination showed that both the cords moved freely. Over the

FIG. 1.



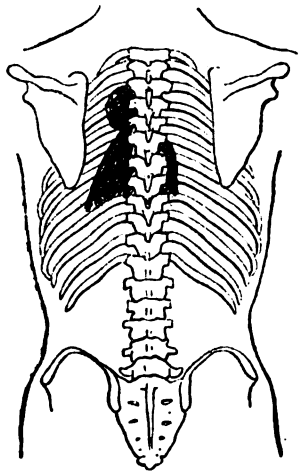
The shadow of the heart is seen extending up the left side of the sternum up to the first rib.

Digitized by Google

upper part of the chest the veins were rather large. Dr. Coupland, under whose care the patient was, suspected the possibility of an aneurysm, and the patient was then examined by the Roentgen rays and a fluorescent screen. The result showed clearly that there was some enlargement of the first part of the aorta, and from the shape it seemed to indicate that the enlargement was fusiform rather than saccular. The appearance is seen in Fig. 1, which shows that the shadow of the heart, instead of terminating at its base in the usual way, has its left border prolonged upwards along the left side of the sternum.

CASE 2.—This case was kindly brought to me by Sir Richard Douglas-Powell. The patient complained of pain in the chest with paroxysmal attacks of coughing and dyspnœa. Physical examination showed that there was a dull area over the upper part of the sternum. Examination by the Roentgen rays showed a shadow corresponding to this area of dulness (Fig. 2). The shadow was not very well marked and its

FIG. 2.

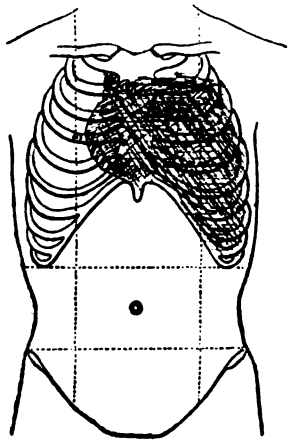


Showing the somewhat indefinite shadow at the level of the second ribs.

outlines were irregular, but it was quite distinct. From its appearance and the various symptoms it was thought that there might be a mediastinal abscess, but subsequent events have made it probable that it is an aneurysm.

CASE 3.—This was a case of aneurysm which I saw on three different occasions with Dr. Bezly Thorne. The patient, a man, aged forty-two years, had signs and symptoms of an aneurysm situated probably in the third part of the arch of

FIG. 3.



The shadow of the aneurysm is seen above the heart on the left side extending from the third to the fifth dorsal vertebra.

the aorta. The principal symptoms were pain, pulsation to the left of the heart in front, and paralysis of one vocal cord. On examination by the rays the posterior view showed the aneurysm very plainly. The shadow was very definite, situated above the shadow of the heart, and its outer border was sharply defined by a well-marked convex border. When viewed from the anterior the appearances were not so plain, but an ill-defined shadow could be seen which was continuous with that formed by the heart. The appearances of the aneurysm are shown in Fig. 3. This case was shown by Dr. Bezly Thorne at the Clinical Society on Feb. 26th, 1897.[1]

CASE 4.—This case, which was kindly brought to me by Dr. Biss, shows the appearance of a new growth in the chest which had displaced the heart. The patient had been under Dr. Biss's observation for a long time, and the symptoms and physical signs made it probable that the condition was that of a new growth complicated by some pleural effusion, though at one time the possibilities of an aneurysm had also been considered. The patient's chest had been tapped twice; the first time some fluid was drawn off, but at the second operation, which was performed a few days before she was examined by the rays, no fluid was obtained. On examining the patient with the rays and a fluorescent screen the left side of the chest was seen to be quite dark as high up as the second rib. Above this level there was a lighter area, but not so light as normally should be, evidently corresponding to the apex of the left lung. The heart was very much displaced; its convex right border was well marked and at one spot reached almost to the nipple line. The origin of the aorta, displaced a good deal to the right of the sternum, was also well seen, and its pulsations were distinctly visible (Fig. 4).

FIG. 4.

Showing the dark shadow of the left side of the chest with displacement of heart and aorta to the right.

I also saw several cases with Dr. Chapman of which I have unfortunately not preserved diagrams. Of course, in all such cases a positive result is of greater value than a negative one, as it may always be said that the aneurysm is either too small or situated in such a position that it did not show, but at the same time when a patient complains of thoracic symptoms and physical signs prove nothing it is in many cases a useful corroboration to know that the Roentgen rays show nothing also, and such a result has in several cases further strengthened the diagnosis.

Queen Anne-street, W.

LACERATIONS OF THE OS UTERI, VAGINA, AND PERINEUM IN SYPHILITIC WOMEN.

BY JOHN A. SHAW-MACKENZIE, M.D. LOND.

MRS. BOYD'S letter in THE LANCET of March 27th, while emphasising the fact that pneumonia is not unfrequently met with in syphilitics, introduces a point which has attracted my attention. I refer to the fact that in women obviously syphilitic, or whose husbands have suffered from syphilis previously to marriage, lacerations of the os, vagina, and perineum are not unfrequent. Such accidents, including uterine rupture, are probably more than coincidences, and

[1] Vide THE LANCET, March 6th, 1897.

Digitized by Google

syphilis may possibly account for such when the accoucheur is in no way to blame. The following cases I have noted.

CASE 1.—A woman, aged thirty-nine years, complained of pelvic pain and backache. She had suffered from discharge for twelve months. She had had eight children; five had died, and there had been three still births and one abortion. She was suffering from prolapsed uterus; the perineum was absent, and she stated that forceps were used in one of her confinements. The pharynx was ulcerated.

CASE 2.—This patient three years ago had a bad confinement and the perineum was torn. She made a tedious recovery, the lochia lasting five weeks. During her pregnancy the hair fell out and she had suffered from ulcerated throat since. The uterus was prolapsed.

CASE 3.—This patient, aged thirty years, suffered from falling womb and discharge since the birth of a child ten years ago. There had been two live births and two abortions. She is subject to sore-throats and the pharynx is ulcerated. The vaginal mucous membrane shows a hyperæmic, patchy, measly condition. The lips of the urethra are in a purple, swollen condition. The perineum shows the cicatrix of previous repair, but is thin and papery, and the uterus is prolapsed.

CASE 4.—This patient, aged forty-five years, had been married twenty-six years. Her husband died from hemiplegia some years ago. One child was born twenty-five years ago, but died in infancy. The patient is now out of health, is suffering from menorrhagia, erosion of the os, profuse leucorrhœa, excoriation of the vagina, prolapse of the uterus, and ulcerated tags of previous rupture of the perineum.

CASE 5.—This patient had been married twice. Her first husband died from cerebral trouble. By him she had four children and one abortion. In three months from the second marriage abortion occurred, followed by eruption on the skin attributed to fish diet. The pharynx and tonsils are now excoriated and the voice is hoarse, while there is scattered acne on the back. Perineorrhaphy was performed after her first confinement.

CASE 6.—This patient complained of agony in intercourse. She has superficial sores of the internal labia, vaginitis, and endometritis. The pharynx is ulcerated and the glands are enlarged in the groin. The cicatrix of a repaired perineum is exquisitely tender to the touch.

CASE 7.—This patient, aged twenty-eight years, complained of pain in the back and groin. She had been married nine years. There had been four live births and one abortion. She had suffered from discharge for eight years. She was regular, but lost a great deal. Her hair fell out during the last conception, which ended in abortion. She had sore-throats at the same time, and the pharynx is now ulcerated. She has always lost a great deal of blood at her confinements. The cervix is split and everted.

CASE 8.—This patient was a woman, aged fifty years. Two girls were born in the first two years after marriage. Then the husband was very ill with "rheumatic fever." An abortion followed, then a live birth, then an abortion, and then two live births. The confinements have always been bad, with six weeks of lochia. After the second girl was born bleeding continued for three months. She now complains of abdominal and rectal pain. On vaginal examination the os uteri was found to be split and tethered to the vagina by bands in every direction, and the rectum is drawn in.

I would point out in connexion with such cases that labour is often protracted from uterine inertia, often necessitating forceps. The post-partum hæmorrhage is profuse and the lochia are prolonged. It is not very uncommon to meet with adhesions of the os uteri to the vagina, of increasing obstructive dysmenorrhœa, and sterility after one conception in parous women. The fibrous adhesions and fibroid condition met with in dilating the cervical canal are well known. Syphilitic stricture of the cervical canal or os uteri is apparently analogous to syphilitic stricture of the urethra in the male, and all the above-mentioned conditions may well illustrate some of the less ostensible symptoms of syphilis in parous women.

A further question follows. Why do plastic operations in women, undertaken with so much care and skill, often fail? The value of mercury in so many cases of pelvic disease in parous women not only testifies to a syphilitic basis, but probably makes it essential that mercurial treatment in many cases should go hand in hand with operative procedure.

Grosvenor-street, W.

A CASE OF ANKYLOSIS OF ALL THE JOINTS WITH COMPLETE CLOSURE OF THE JAWS, IN WHICH THE POWER OF MASTICATION WAS RESTORED BY DIVISION OF THE NECKS OF THE LOWER JAW:

WITH SOME REMARKS ON THE OPERATIVE TREATMENT OF CASES OF ANKYLOSIS OF THE TEMPORO-MAXILLARY JOINT.[1]

BY CHARLES A. MORTON, F.R.C.S. ENG.,

SURGEON TO THE BRISTOL GENERAL HOSPITAL AND PROFESSOR OF SURGERY IN UNIVERSITY COLLEGE, BRISTOL.

A MAN, aged fifty-seven years, was sent to me at the Bristol General Hospital by Mr. W. F. Carter, of Bristol, in October, 1896. In all the joints movement was limited, and in most there was complete fixation. The spine and head were perfectly rigid. Deformity was marked both in the large joints and in those of the hands and feet. In some joints where slight movement was possible there was coarse grating, and around a few joints distinct osteophytic outgrowths were present. Muscular wasting was extreme; the skin of some of the fingers was glossy, and some of the nails were of extraordinary thickness. The thickening of the nails was not present in all the fingers. The joint troubles began fourteen years previously in the knees, and the fingers were affected after the larger joints. He was able to walk with sticks until nine years ago. For the last six years he had been confined to bed and unable to feed himself, and for four years he had been unable to open his jaws and therefore unable to take solid food, and had simply sucked fluids between his teeth. He had had no joint trouble in early life, nor was there any family history of such disease. The following is a description of the condition of all the joints. Both knees were absolutely fixed at a right angle. The bony outline was very prominent from the wasting of the muscles, but no osteophytic growths were discovered. The tendons in the popliteal space did not feel contracted. No movement was detected in either hip-joint. There was limited movement in the left ankle, but the right ankle was almost completely fixed. All the toes of the left foot except the great toe were hyper-extended (some to a right angle with the dorsum), and the heads of the metatarsal bones from which they were displaced could be felt from the sole. The middle three toes of the right foot were in the position of hammer-toes. The nails on several toes were of extraordinary length and thickness. The left wrist was flexed almost to a right angle with the forearm and quite ankylosed. The fingers of the left hand were all flexed at the metacarpo-phalangeal joints, and there was marked deviation to the ulnar side. Movement in the finger joints was much limited. There was marked osteophytic outgrowth about the heads of the metacarpal bones. The nails on some of the fingers were almost normal, on others they formed a horny mass half an inch in thickness, and the skin of the fingers was glossy. There was no grating in any of the joints. The left thumb was also flexed at the metacarpo-phalangeal joint, but was hyper-extended at the terminal one, and movement in its joints was as limited as in the fingers. The right wrist was slightly flexed and very little movement was possible in it. All the fingers of the right hand were hyper-extended at the metacarpo-phalangeal joint, flexed at the middle phalangeal joint, and hyper-extended again at the terminal joint. There was hardly any movement possible in any of the joints, and osteophytic outgrowths were present on the dorsal aspect of the digital extremities of the first phalanges forming the middle phalangeal joint. The position of the right thumb was the same as the left. There was slight grating in its metacarpo-phalangeal joint. The left elbow was quite ankylosed and was much more flexed than a right angle with the upper arm. In the right elbow there was slight movement which was painful, and there were some sharp osteophytic outgrowths from the inner

[1] A paper read before the Bath and Bristol Branch of the British Medical Association.

Digitized by Google

condyle. In the left shoulder rotation was possible to a slight extent, but was accompanied by coarse grating. In the right arm the movement at the shoulder was wholly scapular. There was no movement in any part of the spine, but no excessive bony growth could be detected. The chest only moved slightly on deep inspiration; in quiet breathing the abdominal wall alone moved. There was no evidence of rotation of the atlas on the axis, and it was doubtful whether there was any movement between the atlas and the occipital bone.

There is so much confusion between the terms chronic rheumatism, rheumatic arthritis, and rheumatoid arthritis that it would not perhaps be profitable to discuss at length the nature of the joint lesions, but taking the definite disease which is perhaps most clearly distinguished by the term osteo-arthritis we may inquire whether it was of this nature. The deformity, the coarse grating in the joints, the osteophytic outgrowth, and the glossy skin all point to the disease being a form of osteo-arthritis. On the other hand, true ankylosis, that is, ankylosis which is not merely the result of locking of osteophytic outgrowths, is rare in osteo-arthritis. In this case the fixation of the joints was clearly not due to osteophytic outgrowths, for they were only present around a few joints and were absent in many which were absolutely fixed. I cannot find the record of any case of ankylosis of the temporo-maxillary joints in osteo-arthritis, though they have become ankylosed from traumatism and suppurative arthritis in several cases. The first time the condyle was excised was for osteo-arthritis. There was no ankylosis, but great enlargement of the condyle, producing marked deformity of the jaw. This was Professor Humphry's case, and was published in the *Medical Association Journal* in 1856.[2] In another case (one of Mr. Heath's)[3] there was also enlargement of the condyle, and a bony mass united it to the malar bone. In one recorded case of ankylosis of this joint, to which reference will be again made, the patient had had rheumatic fever and suffered from recurrent sub-acute attacks.[4]

In my own case there was no evidence of enlargement of the condyles, but there was complete fixation of the joint, so that the jaws could not be opened. It was, of course, impossible to tell whether the ankylosis affected one or both joints. To remedy such a condition either the adhesion in the joint must be broken down, or the joint excised, or a new joint formed. It was impossible in this case to lever open the jaws, as the teeth could not be separated at all, and hence no wedge or screw-gag could be introduced; and, moreover, Mr. Paul Swain has shown, from the collected records of cases, that all such attempts fail.[5] A new joint has usually been formed by removal of a wedge of bone just in front of the angle of the jaw—Esmarch's operation. The respective advantages and disadvantages of the two operations I will consider presently. I decided on excision of the condyle or condyles, and the operation I am about to describe was performed in exactly the same way on both sides, as the ankylosis was found to be bilateral. It was done on Oct. 27th, 1896. An incision was made about one inch in length parallel with, and a quarter of an inch below, the lower border of the zygoma, commencing just in front of the ear and extending forwards, therefore beginning over the temporal artery, but not deep enough at that spot to wound it. A portion of the parotid gland, superficial fascia, and fat were divided, and several small vessels were tied. The masseter was then exposed and was divided, and I came down on the zygoma, with the neck of the jaw fixed to it as if it were one bone. There was no sign of any joint, nor could any movement be made out on attempting to open the jaw. I then inserted a curved narrow copper spatula under the neck from behind, so as to separate it from the internal maxillary and other vessels, and divided the neck with an Adam's saw and a few chisel cuts. When I found the joint was completely obliterated I gave up the idea of excising the condyle. I saw no branches of the facial nerve on the right side; on the left, when retracting the fascia over the masseter, the orbicularis palpebrarum and oris both twitched. When separating the divided portions of the neck on the left side with a periosteal elevator some rather free bleeding occurred from a vessel behind the neck—probably a torn venous branch—and I had to leave a pair of pressure forceps on, as it was impossible to tie it. These were removed next day, and the wounds healed without suppuration. After divisions of both necks I was able to lever the jaw open, so that there was a space of a quarter of an inch between the teeth, and a few days after the operation he could open it one-eighth of an inch more and could eat all kinds of solid food. Nearly a month after the operation I opened the jaw with a screw gag under chloroform so that there was nearly an inch space between the teeth. I heard in February of this year that he was still able to eat solid food easily.[6] There was a little paresis of the left orbicularis palpebrarum after the operation, but with the application of the faradaic current this soon passed off.

After excision of the condyle or division of the neck of the jaw the difficulty in forcing open the jaw lies in the contracted condition of the muscles, especially the temporal muscle. After dividing the neck on both sides in this case I found the movement at the point of section free, but the contracted temporal and masseter muscles kept the jaws from separating to any extent, and I had to gradually lever them open in order to obtain a satisfactory result, a process which was repeated some weeks after the operation. I believe that it is best to make only a horizontal incision below the zygoma, and not a vertical one at all, as division of branches of the facial nerve is more likely to occur with the latter, however short, and I believe it would not give a distinctly greater access to the joint than a fairly long horizontal incision.

The respective advantages and disadvantages of excision of the condyle and Esmarch's operation of removal of a wedge-shaped piece of bone from just in front of the angle of the jaw remain to be considered. It seems to me that if we can liberate the joint so that it will not again become fixed it would be much better to do so than to perform Esmarch's operation. After a double Esmarch's operation the body would be quite cut off from the ascending rami, so that the masseters, temporals, and pterygoids could not act on the movable portion, and the ability to close the jaw would be lost; nor could any antero-posterior or lateral masticatory movements be performed. It seems possible that in time the buccinator might partially take on the action of the masseter and be able partly to close the jaw. That the power of closure does return is shown by the records of cases in which the operation has been performed, but it does not become possible for lateral masticatory movements to be carried on. If the wedge in Esmarch's operation is taken out so far back as to include the angle, as has been done in a few cases, then the attachment of the masseter would not necessarily be wholly separated from the movable portion, and closure could be feebly effected by the portion left attached. On the other hand, some surgeons have brought forward this very severance of the movable portion of the jaw from the masseter and other muscles which close the jaw as a great advantage of Esmarch's operation, for it, of course, tends to prevent the divided portions of jaw being forcibly drawn together and so reunited. The most serious objection to operation on the joint is the unfortunate tendency there is for it to become again fixed after operation; and no doubt the temporo-maxillary joint is in a somewhat dangerous locality for operative interference, with the internal maxillary artery so close to it beneath and the branches of the facial nerve lying over it in the way of the necessary incision. Temporary paralysis of some of the branches of the nerve is not uncommon after the operation, and in one case the external carotid artery was wounded.[7] The facial artery might be wounded in Esmarch's operation, but could probably be pushed out of the way, or if divided could be easily secured, whereas the internal maxillary artery if wounded might be very difficult to secure, as it lies behind the junction of the neck and ascending ramus. The inferior dental artery is divided in Esmarch's operation, but does not bleed when sawn through, nor does division of the inferior dental nerve give rise to any trouble. If Esmarch's operation is performed for fixation of the jaw due to a unilateral cause, then the muscles of the side on which the operation has not been performed will, of course, close the jaw, but antero-posterior and lateral masticatory movements would necessarily be very imperfect from the inability of the external pterygoid, masseter, and temporal muscles to act on the side from which the wedge had been removed. We should, indeed, expect the body of the jaw to be somewhat pushed over to the side operated on by the external pterygoid of the

Digitized by Google

other side. It has sometimes happened after Esmarch's operation on both sides that the power of swallowing has been interfered with from loss of a fixed point for action of the elevators of the hyoid bone when the body of the jaw has been detached from the rami. A case under Mr. Bennett's care[8] so well illustrates the advantages and disadvantages of Esmarch's operation and excision of the condyle that I will give a short abstract of it. The patient suffered from complete fixation of the jaw. Mr. Howse, at Guy's Hospital, exposed both temporo maxillary joints, finding very firm ankylosis, and excised both condyles. The joint again became fixed, and Mr. Howse then removed a portion of one ascending ramus, but this subsequently united. Mr. Bennett then performed Esmarch's operation on both sides with a week's interval. The jaw opened after the second operation, but the patient was quite unable to close it, and as the elevator muscles of the hyoid bone had no longer a fixed point of attachment he became unable to swallow and had to be fed by a tube passed through the nose and down the pharynx for two days. The jaw was then fixed in position by an elastic bandage and the power of swallowing returned. The power to close the jaw also ultimately returned. Mr. Paul Swain reports[9] a case of bilateral ankylosis in which he removed a triangular piece of bone from both angles of the jaw at one operation with very satisfactory results. There was no interference with swallowing, and no mention is made of inability to close the jaw. Doubtless some anterior fibres of the muscles were attached to the lower jaw in front of the section of the bone, and enabled the patient to close the jaw, and thus give the hyoid muscles their fixed point for action. There are, of course, many cases in which we have no choice between an operation on the joint and Esmarch's operation—cases in which the jaw is fixed by a dense cicatrix such as may follow cancrum oris or injury to the cheek or jaws. In such cases we must make a false joint in front of the cicatrix, but they are almost always unilateral.

Mr. Paul Swain has collected[10] the records of twenty cases of operation for closure of the jaws the result of injury or disease of the temporo-maxillary articulation. He found that out of this number seven resulted from the after effects of scarlet fever, three from measles and subsequent otorrhœa, three from rheumatism, two from affections of the teeth, and five from injury. In eleven cases the condyle or a portion of the neck was excised, and in five Esmarch's operation was performed. To the cases collected by Mr. Paul Swain must be added four recently published by Mr. Arbuthnot Lane.[11]

CASE 1.—Bony ankylosis after fracture of the zygoma. The upper and posterior angle of the jaw with a portion of the temporal bone to which it was fused was excised with good result.

CASE 2.—Bony ankylosis from old suppurative arthritis, with very imperfect development of the jaw. The same operation was performed, and the body of the jaw was divided as well to overcome the deformity. The result was good.

CASE 3 —Bony ankylosis after scarlet fever. Same operation and result.

CASE 4.—Bony ankylosis after abscess in the neighbourhood of the jaw. Same operation and result.

All these patients were children. Mr. Lane has operated once in an adult and obtained a very good result for a time, but relapse took place and he had to remove more bone. He lays stress on the difficulty of thoroughly free removal of bone in these cases, as all trace of the joint has disappeared and the neck is ill developed, but believes that it must be freely removed to ensure a successful result.[12]

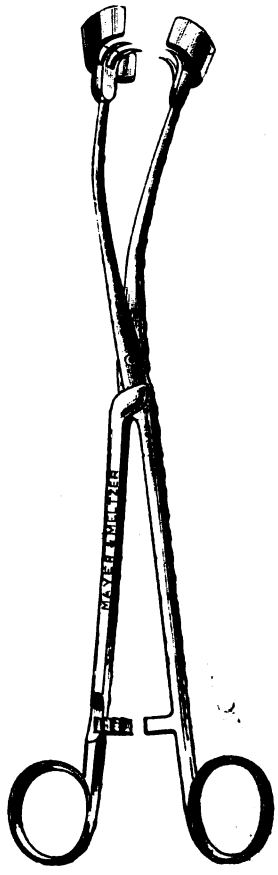
[12] Since sending this paper for publication a very valuable contribution from Dr. Cabot, of Boston, on the Surgical Treatment of Ankylosis of the Temporo-maxillary Articulation has been published in THE LANCET of Aug. 7th, p. 304, and I am interested to see that Dr. Cabot advocates division of the condyle in preference to Esmarch's method, and records seven cases in which he performed this operation.



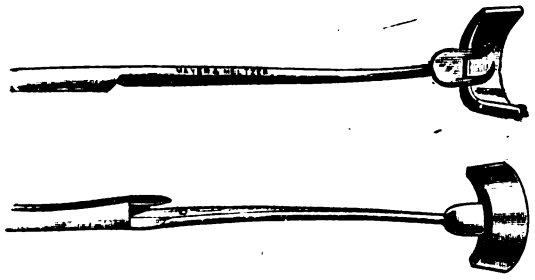
DR. GRANVILLE BANTOCK has been elected an Honorary Fellow of the Obstetrical Society of Edinburgh.

NOTES ON A CASE OF PAN-HYSTERECTOMY.

BY M. U. O'SULLIVAN, L.R.C.P. EDIN.

I AM sure that every surgeon of experience in the operation of abdominal pan-hysterectomy will admit at once that the chief difficulties are encountered in dealing with the floor of the pelvis and roof of the vagina. It has long appeared to me that a suitable vaginal guide would not only materially facilitate operative technique at this juncture, but would obviate the danger of encroaching too much on the roof of the vagina. In my first six cases of complete extirpation I resorted to the abdomino-vaginal method, commencing the operation as in the first stage of vaginal hysterectomy; but this method is open to the objection that upon opening the peritoneal cavity some special indication may be found against completing the operation on the lines originally intended, leaving the patient with a vaginal wound to still further hamper her recovery. Mr. Bowreman Jessett, in this operation, used a Ferguson speculum, pushed up by an assistant as a guide; but the difficulty—or, rather, I should say, the hopelessness — of keeping the vaginal cervix in the vast majority of "fibroids" within the lumen of a speculum is at once obvious. Other surgeons have used the finger of an assistant pushed up into the vagina as a guide to cut down upon, but this is a procedure not likely to recommend itself to the precise and careful operator. The vaginal forceps (Fig. 1) and director, of which illustrations appear, has been used in four cases with much advantage to the patient and with the greatest satisfaction to myself. It was made after my direction by Messrs. Mayer and Meltzer. I give the notes of one case.

FIG. 1.



A woman, aged forty years, single, was admitted to the Women's Hospital, Melbourne, on July 8th, 1896. The catamenia first appeared at the age of twelve years; she was regular up to two years ago, but the menses had been irregular, profuse, and painful during the past two years. During the past three months she had complained of severe pain in the right iliac fossa and sacral region, frequency and pain in micturition, bearing down, &c. On examination, a rounded median tumour of hard consistence could be felt filling the pelvis and extending above the umbilicus. The cervix uteri was pushed far back in the hollow of the sacrum. The patient was prepared as for cœliotomy and vaginal hysterectomy and was placed in the lithotomy position, the lower limbs being separated by assistants. A Sims speculum was passed, and the vagina thoroughly scrubbed with a 1 in 500 perchloride solution. The cervix was now grasped with the combined vaginal forceps and director, the blades of which were firmly locked and the patient returned to the supine position. The abdomen was opened by a free incision extending from above the umbilicus to within a short distance of the pubes, and the tumour "delivered"—this being very materially facilitated by an assistant steadily pushing the tumour and uterus towards the abdominal cavity, on the forceps and director, within the

Digitized by Google

cup-shaped end of which the cervix sits, firmly held. (And here) I would claim that there is a decided advantage in being able to dispense with, in many cases, the ponderous prehension forceps generally used for elevating uterine fibroids through the abdominal wound during operation, and

FIG. 2.

Forceps with blades unlocked.

so preventing the annoying hæmorrhage which sometimes takes place from forceps punctures of such tumours.) The broad ligaments were divided between two rows of ligatures, and the usual peritoneal flaps dissected down off the anterior and posterior surfaces of the uterus with blunt scissors and finger. The uterine arteries were now easily picked up on an aneurysm needle and secured outside the reflected peritoneum. The vagina was opened by running a knife around the cervix, within the hollow of the vaginal director, which was still steadied by an assistant and easily felt. Now, instead of suturing the peritoneal flaps as I have done in previous cases, I passed about half a dozen long silk sutures through the edges of the peritoneal flaps and drew them into the vagina, thus completely closing the peritoneal floor. With a Sims speculum the vagina was now well packed with iodoform gauze, firm traction being kept on the flap sutures during the packing. The abdominal wound was closed with deep silkworm gut and superficial horsehair sutures. The vaginal packing was removed on the fourth day after operation, and the sutures on the eighth day. The patient made a perfect recovery and left the hospital on Aug. 27th, 1896.

Melbourne.

A CASE OF HEMICHOREA WITH APHASIA.

BY S. J. ROSS, M.B., CH.B. VICT.,
RESIDENT HOUSE SURGEON, BEDFORD GENERAL INFIRMARY AND FEVER HOSPITAL.

A GIRL, aged fourteen years, at the age of eight years had had an attack of acute rheumatism which left traces behind in the form of well-marked mitral regurgitation. A week before being seen she was thrown from a cart, and on the day following the accident her mother noticed that her right arm and leg were constantly in motion and she was restless and never answered questions put to her. Thinking "she was merely shaken" she was put to bed, her parents hoping that by taking rest she would soon be well again. However, as she did not improve I was asked to see her seven days after her fall from the cart. Her condition at this time was as follows. She was in a condition of marked cerebral instability, now laughing and the next minute in tears. Her pupils were dilated. There were marked choreiform movements in the right arm and leg. The tongue was protruded with a jerk and as suddenly withdrawn. The knee-jerk on the right side was exaggerated; on the left side it was normal. Sensation was normal. There were marked cardiac irregularity and a mitral systolic murmur conducted to the back, with accentuation of the pulmonary second sound. On being asked questions the patient simply nodded assent or dissent. The movements ceased during sleep.

The treatment adopted was absolute rest, milk only, arsenical solution in increasing doses—as diet at one time she was taking ten minims three times a day—and occasional purgatives. In six weeks she was on full diet and had perfectly regained her power of speech.

Remarks.—A case such as this points clearly to the cerebral origin of the lesion. The emotion and cessation of movements during sleep, the exaggerated right knee-jerk and aphasia, point clearly to a lesion on the left side of the brain, not permanent, but functional, or at any rate capable of complete resolution. What the exact pathological change may be is not known, and, indeed, we must be left in doubt as chorea is a disease so amenable to treatment. Gowers suggests a lowered resistance on the part of the cerebral cells. If this be true it is curious that in cases such as this of true hemichorea this lowered resistance should be limited to the cells on one side of the brain. Others have suggested a rheumatic inflammation of the cerebral neuroglia—a neurogliosis—these nodules corresponding to the periosteal nodes so frequently found along bones such as the tibia. Whatever the exact pathological change may be it is certainly curious that arsenic should have absolute control over it—a control which no other drug possesses, except, perhaps, in those cases of convulsive or epileptiform varieties of chorea when a combination of chloral hydrate and bromide of potassium is the most successful treatment, at any rate at first, arsenic frequently being resorted to after the convulsive stage has passed. In offering these remarks of course I do not include that form of nervous disturbance which is often called post-hemiplegic chorea, but which ought rather to be called post-hemiplegic mobile spasm, as suggested by Gowers.

A CASE OF OBSTRUCTIVE SUPPRESSION OF URINE.

BY F. GRAHAM CROOKSHANK, M.D. LOND.,
LATE HOUSE PHYSICIAN TO THE BROMPTON HOSPITAL.

A LITTLE girl, aged eleven years, was brought to the Brompton Hospital for Consumption and Diseases of the Chest in a state of collapse, the mother stating that almost incessant vomiting had occurred for a week; the bowels had been confined during that period. The aspect was suggestively abdominal, and the case appeared to be one of intestinal obstruction. The patient was at once admitted under Dr. Green, who has most kindly allowed me to write this account. The more complete examination then possible failed to detect any abdominal tumour or evidence of peritonitis. The child, although drowsy, was quite conscious; the temperature in the axilla was 96° F.; the pulse 120 per minute, small and thready; and the respirations were 25 per minute and shallow. On auscultation an apical systolic bruit and moist râles, with friction sounds at the posterior bases of both lungs, were heard. There was no œdema. Spasms of the levatores palpebrarum and internal recti occurred every few minutes, but no other muscular twitchings were noted. The tongue was very foul and the breath was urinous. Further inquiry elicited the fact that three years previously an operation—details of which I have been unable to ascertain—was performed for an abscess of the right kidney. Two years previously there had been a severe illness, lasting several days, the prominent feature of which was agonising pain in the loin. For the last ten days or so there had been much headache, and for a week frequent vomiting. For at least five days prior to admission no urine had been passed, and for several months previously the child had passed urine only at comparatively long intervals (twenty-four hours or more), and then with pain. During the night after admission seven and a half ounces of turbid urine were passed. The urine was acid, of specific gravity 1020, gave a heavy precipitate with picric acid solution, and contained many pus cells, but was without either casts or blood. No more urine was passed during life, and after death the bladder was found to be empty. Vomiting occurred four or five times during the following day, and the spasms of the ocular muscles happened as frequently as before. The pupils were equal and slightly dilated. The child rallied slightly on the whole; the pulse improved, and the rectal temperature rose to 98°, and subsequently to 100°. Towards night the respirations, which had been tranquil, became hissing in character, and the rate rose to 30 or 35 per minute. The drowsiness increased at the same time. By the early morning these symptoms had passed off, but only to recur with greater severity for an hour or two before death, which took place rather suddenly

Digitized by Google

forty-eight hours after admission. Vomiting had taken place about a dozen times in the two days. The child was conscious, and answered questions two hours before death. The only symptom that developed under observation was the hissing character of the respirations.

At the necropsy, which was made by Dr. Habershon, there was found general acute pleurisy, with a deposit of thick yellow lymph over the lower lobe of each lung. The heart weighed four and three-quarter ounces, and the wall of the left ventricle was thickened without any obvious valvular lesion. In the place of the right kidney there was found a mass of fat and fibrous tissue which on section displayed a smooth cavity three inches in length, connected with which were one or two much smaller cavities. These cavities, which obviously represented the pelvis and calices of the kidney, held a few drachms of brownish fluid. A few islets of renal tissue were found scattered in the fat and fibrous tissue. The right ureter (four and a half inches in length) was moderately dilated, and its opening into what had been the pelvis of the kidney was completely blocked. The wall of the bladder was three-quarters of an inch in thickness, and the whole organ was hypertrophied without any obvious dilatation. The mucous membrane of the bladder was deeply congested and much pigmented. The left kidney was enlarged, four inches in length, and the pelvis and calices were much dilated. The pyramids were flattened to a thin layer, and the cortex, which was not congested, was slightly fatty and about three-eighths of an inch in thickness. The capsule was not unduly adherent. The first two inches of the left ureter below the pelvis of the kidney were dilated, admitting the little finger with ease. The pelvis and calices of the kidney and this portion of the ureter were distended with clear, urinous fluid. At two inches from its point of origin the ureter was narrowed and the mucous membrane for half an inch vertically was much puckered as if by cicatrisation. A horizontal fold of mucous membrane here formed a valvular, but complete, obstruction which could only have been overcome by dilatation of the narrowed portion of the ureter. Below the point of complete obstruction the ureter was again dilated and tortuous, its total length being six and a half inches. The ureter below the obstruction contained no fluid. Probably when the pressure of urine accumulated above the valve reached a certain degree the narrowed portion of the ureter yielded, allowing urine to escape through the valve. The fatal issue must have been due to the fact that finally the obstruction could not be thus overcome, and the pressure of urine accumulated above it had reached the point at which (according to the general view of the pathology of suppression in these cases) further secretion of urine was no longer possible.

The readiest explanation of the anatomical facts seemed to be that the stenosis and puckering were the result of a cicatrix following injury to the ureteric wall from the passage of a calculus, presumably at the time of the illness two years previously. To the obstruction, which must necessarily have been intermittent only until the last week of life, was due the dilatation of the kidney and first part of the ureter. The dilatation of the lower part of the left ureter may have been due to the obstruction afforded by the hypertrophied wall of the bladder. There was no anatomical evidence that regurgitation of urine from the bladder into the ureter had occurred. I have been unable to ascertain whether or no the "abscess" of the right kidney was due to stone. Probably it was. The hypertrophy of the bladder may have resulted (as in diabetes) from the increased quantities of urine it had been called on to discharge from time to time; but the chronic cystitis suggested a more likely cause—namely, that a stone had been retained in the bladder, setting up intermittent obstruction at the neck. The parents could give no information on this as on several other points, beyond stating that the urine had frequently smelt foul and that its passage had given rise to pain.

Although the interpretation of the case in several respects is uncertain, there can, I think, be very little doubt that death was due to obstructive suppression of urine. Clinically, there were two points of difference from the description usually given of such cases—(1) it was the urinous smell that first suggested the correct diagnosis; and (2) the vomiting was so severe as to suggest intestinal obstruction. In another case that I have seen (in which simultaneous plugging of the ureters by calculi had occurred), vomiting was so grave a symptom as to lead to the diagnosis of intestinal obstruction. Sir William Roberts states that an urinous smell is hardly ever, and persistent vomiting seldom, a symptom of obstructive suppression of urine. It is not easy to see why the symptoms of this form of suppression of urine should differ so widely from those of non-obstructive suppression, or why life should be, in the one group of cases, prolonged for such relatively long periods after secretion of urine has ceased without coma supervening. It is generally recognised now that the kidney has other than purely excretory functions, and it is perhaps possible that in obstructive suppression it is the excretory function only or chiefly that is in abeyance, while in non-obstructive suppression all renal functions are suspended. There is experimental evidence which goes some way towards proving that urine ceases to be excreted when the pressure of urine in the pelvis counterpoises the pressure in the renal arterioles. If this be the mechanism of suppression in the obstructive cases, it is quite possible that under such conditions the kidney cells might continue their metabolic (internal secretory) functions. But when such organic disturbance of the renal cells occurs as must be the case in acute nephritis leading to suppression of urine, it is hard to see how any renal functions whatever can be efficiently performed. If this view be in any degree valid we have perhaps some explanation of the difference in symptoms between the two classes of cases of suppression of urine.

Leysfield road, W.

INFLUENZA.

BY GEORGE GRESSWELL, M.A. OXFORD AND CAPE OF GOOD HOPE, L.R.C.P., L.R.C.S.EDIN., L.F.P.S.GLASG.

THE recent extensive acquaintance with epidemics of this disease in a virulent form, not only in this country, but throughout the world, is perhaps one of the most instructive and important experiences of the last few years. True it is that, looked at from one aspect, influenza may be classed as a minor scourge. It is well that this is so, because science seems as yet almost completely powerless in arresting its spread. As a rule, when properly managed and skilfully treated from the outset, patients do not succumb. Unless dangerous complications are present at first or arise in the course of the complaint the percentage of deaths is only small. Nevertheless, as is well known, very large numbers of people have been affected and rendered incapable. Not only is it the case that whole communities are liable to be stricken down, but it is also a fact that the victims are prostrated with marked nervous, febrile, and catarrhal symptoms, and are afterwards liable to be attacked with distressing and debilitating sequelæ.

One of the most important points is that symptoms pointing to implication of the nervous system are produced, although it has been in past times held that influenza is essentially manifested by a specific kind of inflammation of the respiratory and alimentary tracts almost exclusively, affecting sometimes in chief part either the one or the other of these, or at other times both either coincidently or consecutively. Now we know from repeated practical experience that we must include the nervous system as liable to be attacked quite as readily as either the respiratory or the digestive system. In fact, we must really look upon it as a general infection of the whole system, the blood no doubt being the medium of the distribution of the poison to all parts. However, it often appears to be the case that the one or the other of these two systems may be the primary seat of manifestation. In reality, then, we are considering a specific fever with well-known symptoms, now practically very familiar. As for the temperature, it may be high, and as a rule in all severe cases the mental collapse is so extreme that to the sufferer it may well seem that even death would be preferable to such misery as is experienced. Yet, although not only its origin from infection, but also its pathology, are extremely simple, the disease may well be termed a protean malady, since so many degrees of severity and so many apparently distinct forms does it assume. It is not, however, difficult to understand why this malady should affect in divers ways different people and the same person under dissimilar conditions. As a matter of fact, all diseases are liable to variations of type, as is well known; but this is more strikingly shown in the case of influenza, partly, perhaps, on account of its very wide and almost

Digitized by Google

universal distribution, and principally, perhaps, because there is scarcely a part of the system which is not vulnerable to its virus.

The rashes of influenza cases are confusing and apt to mislead; and I have seen a girl with a rash like that of typhus fever where there was probably nothing but a very bad attack of influenza. However, no importance can be attached to one such rash. On the other hand, cases repeatedly arise where we have little more serious to deal with than the simple coryza which undoubtedly may arise from a chill or benign cold. Probably such mild influenzas might, after all, be caused by an attenuated virus, for no doubt such germs are practically omnipresent in the air to a greater or less extent—at any rate, during epidemics. Similarly one may mention the two kinds of chancres, benign and malignant, the two kinds of psoriasis, the two kinds of diphtheritic throats, perhaps similarly related.

Horses, and probably most other animals, including cats, which probably often serve as channels of infection, are liable to attack. It seems to be without doubt carried through the air, and probably by the prevailing winds for long distances. Its progress is irresistible, and there is no known method of escaping from the infection. That the malady can be wafted over seas, oceans, and lakes seems at least probable, for many cases are known of sailors far away from land being affected. Unless the period of incubation be a very long one—a supposition we do not like to admit without very good proofs—we have no other very likely explanation of such examples, except, indeed, the possibility of clothes carrying the germs of the disease, and then a chill or exposure to cold rendering the object of attack vulnerable To this we prefer the air-borne theory of transmission. We all recollect how, although we were well prepared by the newspapers for its expected appearance amongst us, many of us did not at first recognise the early indications of its presence in our midst. Very soon, however, as case followed case, it was very clear that we had to deal with a specific disease more important than the perennial epidemics of ordinary colds. This fever which was ravaging the whole country manifestly presented some peculiar and hitherto unfamiliar features. A very large number of cases presenting all degrees of severity came under the treatment of every practitioner, and we soon learned to recognise the cases at once, and their correct management and treatment was simple enough, the only difficulty being that the medical man himself was sure to be affected sooner or later, and it is no exaggeration to say that most of us were nearly worked to death, and not a few actually died in consequence of carrying on work when incapacitated.

It has often passed current as true that a low state of the general health made one more liable to attack. This is a statement which, however probable it may appear to be as an *a priori* assumption, is not consistent with facts. It is in short an inference for which there is no foundation. Indeed, the healthier one may be the more likely he will be, if exposed to a sufficient degree of infection, to fall down a victim. The strongest and most robust agricultural labourers living a healthy and regular life were readily affected, especially, perhaps, in cold and wet weather. One attack, so far from conferring immunity, seems to render an individual more prone to subsequent infection, provided a short interval has elapsed. In other words, any immunity which there may be is of the most transient nature. There are very few people who have not suffered from influenza, and even many of these may have really had it in a mild form without its true nature being recognised, or, if not, they may look upon it as a probable treat in store. Most persons have had it more than once, whilst many have repeatedly been afflicted, some, like myself, so frequently that they have lost count of the exact number of times. All those who are liable to be brought into relation with patients suffering from this malady should exercise the greatest care, not only to prevent themselves getting the disease, but also to carry out such measures as would be likely to destroy the germs before they really gained a hold over the system, and thus cut short the infection. One of the very worst attacks I have personally had arose as a result of a professional visit to a very bad case. At this time, having recently returned from a short holiday and being in very good health (so that it seemed almost impossible to catch cold), the only precaution I took was washing carefully and smoking. These measures were not sufficient. It has been held that the period of incubation varies from a few hours to even as long as three weeks. In all probability it is usually only a few hours, and seldom or never more than a day or two. Any evidence of a more prolonged period is vitiated by the fact that it is impossible in nearly all cases to exclude the idea of another source of infection.

It is also said that the invasion may either be gradual or sudden; but in most cases influenza is rather abrupt both in its onset and in its subsidence. A not uncommon first sign of attack appears to be an itchiness and smarting of the eyes and eyelids. The patient feels inclined, in consequence of this uneasiness, to rub the eyes. This itching is apparently caused by a catarrh of the conjunctivæ and is soon accompanied by a copious watering of the eyes. The catarrh very quickly extends to the nose and spreads rapidly downwards, the nasal cavities feel hot and dry, and soon a watery, acrid discharge flows profusely, causing repeated sneezing, and frequently a very uneasy feeling of stoppage and obstruction in the nasal cavities (coryza). Then there are chills or rigors and great misery, lassitude, and prostration, and not uncommonly a feeling of impending death. There is, as a rule, an intense and most painful headache, generally frontal, and perhaps due in part, but not entirely, to congestion of the membrane lining the frontal sinuses. The aching is not always confined to the frontal region. Any part, or, indeed, the whole head, may ache. There is nearly always a feeling of nausea, often actual vomiting, which may be most violent and uncontrollable (comparable even to the violent vomiting which may usher in an attack of small-pox or other specific fever). Pains in the body and limbs may supervene, either very shortly or perhaps the next day. The patient often complains of aching all over, and so great is his misery that he may even long for death to end his sufferings. As for the temperature, it may be normal or only elevated a little, perhaps about one degree or a little more, or it may rise more or less rapidly as high as 104° or 105° F. The skin may either be hot and dry or it may be moist and bedewed with a sour perspiration. The urine may be, after standing, cloudy with deposit of urates, and frequently it is very bad indeed in this respect, being like very muddy water; the sneezing may soon cease or may continue for a day; the power of smell and of taste is impaired; there is a sense of severe dejection, and very likely a very profuse discharge from the nostrils, which may be so copious as at times almost to occlude the nares, and no doubt this excretion augments the headache. Soon sore-throat (mouth, tongue, pharynx, and trachea) and hoarseness come on. At first the throat may be dry, but soon there is expectoration, which extends until bronchitis supervenes. Looking at the back of the mouth one is struck with the intense redness, due to engorgement of the small blood-vessels. This colour is generally demarcated rather sharply just in front of the pillars of the fauces, and forms a striking contrast to the appearance of the tongue, which may be whitish or yellowish white or of a nasty virulent yellowish hue, generally with thick, sticky, moist fur, not like that of ordinary torpidity of the liver, but something almost characteristic and to some extent even diagnostic. Sometimes the tongue is more like that of scarlet fever, being dotted with numerous white spots. Again, in other cases the tongue may be quite clear. This appearance is coupled with a feeling as if the throat had been powerfully scarified with a blunt and rusty knife or old saw. This feeling, though imperceptible in its growth, is worst at an early time of the disease, during the engorging of the blood-vessels and before the redness is best shown. In other words, when the congestion has really occurred the feeling is not so bad. There may be pain along the Eustachian tube, coupled with some deafness. About the lips there is often a herpetic eruption, and a rash often appears on the cheeks, neck, and chest. As a rule the patient is thirsty and has no appetite for food. There is nearly always great prostration and helplessness. At first there may even be inability to get into bed, or at least difficulty in doing so, and, in addition, severe physical discomfort may be experienced. One feels inclined to lie down in sheer exhaustion after the restlessness of the febrile stage has passed, and, as above said, even death may seem to be imminent and desirable to the sufferer. There may or may not be a feeling of oppression across the chest, and severe aching and shooting pains in the head, neck, chest, back, limbs, and abdomen are not unusual. Coupled with the epigastric pain and tenderness (from which the title "la grippe" derived its applicability) there may be nausea and vomiting, and perhaps diarrhœa or constipation. Giddiness and restlessness may be present. It

Digitized by Google

is not an uncommon occurrence in severe cases for the sufferer to be suddenly struck down helpless, thus presenting a great similarity to the effects of an apoplectic stroke. A case of pure influenza, very much like one of cerebral apoplexy, was that of a woman of mature age, who was attacked with the disease whilst walking in the street homewards. She had been taken into an inn, and was lying quite helpless on the sofa when I arrived, and was almost unconscious and not able to satisfactorily reply to questions. After partially coming to this patient had to be sent home in a cab. This was really nothing more than a sharp seizure of the disease under consideration, yet there was in all probability meningitis and cerebral congestion in this as in several similar cases. It was not only in persons of mature age, nor in the weak, infirm, and unhealthy, nor was it in the intellectual classes that these marked nervous phenomena generally occurred. Another instance was a strong young man who, when I arrived, was similarly prostrate, dazed, and helpless, with the tongue very markedly furred with a nasty yellow covering. He had to be practically carried upstairs to bed, as he had lost nearly all power of movement. Delirium, stupor, and convulsions may occur, and stupor is often shown. In one case, or I may say in two, though I have some doubts as to the exact causation in one of these, continued drowsiness, and, indeed, actual sleep, occurred for the best part of three and a half days. There was in the case which I am clear was one of influenza no danger whatever; but this sleep was uncontrollable, and, indeed, seemed necessary for recovery. These were both young girls. The one about whom I am certain is now married, and I saw her a short time ago and referred to this influenza-sleep which occurred some few years ago. It was a peculiar case, and the sleeping was perfectly genuine. With regard to the pulse, it is as a rule frequent, full, and bounding, but it generally soon becomes soft, weak, and slower.

With regard to prognosis, very early or advanced age, or chronic pulmonary or cardiac disease, and especially, perhaps, nervous complications, render the disease grave. It is very questionable if it is scientific or even wise to make a classification of varieties; but, speaking quite generally and from ordinary practical experience, we may mention four chief types: (1) pulmonic; (2) abdominal; (3) neurotic; and (4) rheumatic. The only or chief merit of this classification is its usefulness. Often a case is met with which does not belong to any of these classes in particular, but presents symptoms of all four types. There is also a malignant form of influenza which may be called typhoid, and, indeed, it is sometimes very difficult indeed to distinguish it from true typhoid fever, especially if the latter begin, as it often does, with a pneumonia. Sometimes, in order to be on the safe side, it seems best to treat such doubtful cases as if they were really typhoid fever in regard to the wisdom of abstention from solids. So puzzling in practice are some of the cases that the question may arise: Is it just possible that there may be some connexion between typhoid fever and typhoid influenza, that the germs of the one disease may be a modified variety of the other? On the whole, it is perhaps wisest to recognise the diseases as distinct.

Perhaps the most characteristic feature of influenza is the intense nervous prostration and feeling of utter helplessness and misery it causes. In most cases presenting any serious symptoms it is quite unnecessary to tell the patients to go to bed, for frequently they can not only not stand, but not even sit down with comfort. In some the prostration is excessive, as it was in a woman under my care who remained in bed for about ten days with an average temperature of 102·5° F., scarcely able to take anything except effervescent or lemon drink and barley water, unable to sleep without the aid of sulphonal or bromides or other sedatives, vomiting and purging persistently whenever any food was taken, and constantly racked with headache and pains in the limbs.

In regard to the important matter of treatment, it may be said to be unwise to adhere to any fixed line. Some authorities condemn the system of treating symptoms; but in reference to influenza special regard must be paid to them. It is above all things necessary to watch the case well and alter the remedies used directly there is need for so doing. On constant watchfulness and care depend our hope of best success. The presence of uric acid in the system should be combated with alkalies. The bowels must be opened daily and diarrhœa checked; vomiting also should be arrested. Where there are lung symptoms, poulticing the chest should be judiciously carried out, and when there is much abdominal pain this is also a very useful measure. Hot flannels with turpentine or some special embrocation, or warm anodyne fomentations, may be substituted. The dieting and general hygienic management are of importance, and at first all solid food should be rigidly prohibited. Antifebrin, phenacetin, citrate of caffein, and gelsemium in small doses are invaluable, when properly used, to arrest the headache. Salicylates, coupled with salts of ammonium and bicarbonates of the alkalies, mingled when necessary with the best cough mixtures, in order to allay the soreness of the throat and the distressing cough, may be advised, with due regard to all the circumstances of the particular case under consideration. Stimulants, such as brandy, whisky, port wine, &c., may be prescribed with care, especially to the old or feeble. Quinine cannot be recommended until the stage of convalescence is reached. The air in the room should be kept pure, if necessary by opening the windows, taking care to avoid draughts. It is also well to have disinfectants about, and it may even be advisable to burn a little sulphur or disengage some sulphur dioxide by other means. The patient may inhale a little iodine from time to time or ammonia from a bottle containing either of these substances. Creosote or eucalyptus or carbolic steam may be preferred, or steam with ether, chloroform, or conium. The patient should keep to bed so long as there be any serious symptoms. With absolute rest in the recumbent posture and fluid diet recovery will be quicker. In adults a dose of calomel is often advisable. The food at first should consist of beef-tea and milk with cold, or iced, or effervescent fluids. Soon the diet may be extended; should capillary bronchitis or symptoms of pneumonia appear decoctions of bark and chloric ether with camphor and ipecacuanha, and some of the usual syrups, as well as stimulants, may be useful. If the pains are severe in the limbs, a larger dose of bicarbonate of potassium may be coupled with some opium, and also with iodide of potassium and salicylate of sodium, or a mixture of bromides may be serviceable. If the temperature be high, sponging with cold or tepid water is very valuable or with a solution of permanganate of potassium. If the headache be severe, cold applications or vinegar cloths may be placed on the painful part, and in some cases two or three leeches are very effectual; indeed, sometimes even one leech acts like a magic charm. During convalescence tonics—e.g., gentian, iron, or quinine, or syrup of the hypophosphites with good food and wine—are advisable. Should there be much debility left after recovery it is wise to order a complete change, if it be possible.

Most patients, however, make a very good recovery, and it is generally only those who have not been properly attended to, taking perhaps no medicine at all, or only such household remedies as are in general use, or perhaps other equally inefficacious nostrums, who are troubled with those interminable complaints which are often traced to the time "when I had the influenza."

New Clee, Great Grimsby.

WE have received a copy of the second and revised edition of "The Blazon of Episcopacy," by the Rev. W. K Riland Bedford. This book, which is published by Henry Frowde, at the Oxford University Press, contains an account of the arms borne by or attributed to the archbishops and bishops of England, including Wales, and will interest those of our readers who are of an archæological turn of mind. Students of heraldry are familiar with the fact that many arms are based on puns, and Mr. Bedford's book furnishes some excellent examples—for instance, the arms of Archbishop Herring (Canterbury), show three herrings; of Archbishop Moore (Canterbury), three negroes' heads; of Bishop Horsley (St. Asaph), three horses' heads; of Bishop Harewell (Bath and Wells), three hares; of Bishop Bull (St. David's), three bulls' heads; of Bishop Alcock (Ely), three cocks' heads; of Bishop Cox (Ely), three cocks; of Bishop De Wingham (London), two wings; of Bishop Salmon (Norwich), three salmon; of Bishop Hinds (Norwich), three hinds; of Bishop Sheepshanks (Norwich), a lamb; of Bishop Dove (Peterborough), four doves; of Bishop Towers (Peterborough), a tower; of Bishop Fisher (Rochester), a dolphin; of Bishop Spratt (Rochester), three sprats; of Bishop Cotton (Salisbury), three hanks of cotton; of Bishop Horne (Winchester), three horns; of Bishop Maydenstun (Worcester), a maiden's head; of Bishop Bell (Carlisle), three bells; of Bishop Kite (Carlisle), three kites' heads; and of Bishop Man (Sodor and Man), five human heads.

ON A SIMPLE METHOD OF MEASURING THE ALKALINITY OF THE BLOOD.

BY A. E. WRIGHT, M.D. DUB.,
PROFESSOR OF PATHOLOGY, ARMY MEDICAL SCHOOL, NETLEY.

PRELIMINARY CONSIDERATIONS.

BEFORE embarking upon the description of the method of measuring the alkalinity of the blood which is to be dealt with in this paper it will be profitable briefly to discuss the following series of questions:—

1. *What is the meaning of the term "alkalinity"?*—It is not by any means sufficiently realised that the term alkalinity is an eminently ambiguous term. It is a term which may at one moment be employed to denote the quality of consisting of, or containing in solution, a free base, while at another moment it is employed to denote quite a different thing—to wit, the quality of consisting of, or containing in solution, bases which are only very loosely combined with acids.

2. *In what sense is the blood an alkaline fluid?*—The blood is an alkaline fluid not in the first, but only in the second sense of the term. It is, in other words, an alkaline fluid only in the sense of being a fluid which contains bases which are conjugated with very weak acids.

3. *What is our criterion of the alkalinity of a fluid which does not contain free bases?*—It will be obvious to consideration that the only possible criterion of alkalinity which is applicable in the case of a fluid which does not contain free bases is the capacity of such a fluid for yielding up bases to weak acids. This capacity of yielding up bases to weak acids is precisely the quality which is tested by indicators.[1] It follows therefore that our criterion of the alkalinity of the blood is the reaction of blood to an indicator.

4. *What is our measure of the alkalinity of the fluid which does not contain free salts?*—It is a corollary from what has been said above that we can obtain a measure of the alkalinity of such a fluid as the blood by determining what amount of acid addition will tie up all its bases in combinations from which indicators (or, as we may more properly call them, "indicator-acids") will be unable to withdraw them.

The theoretical groundwork of all hæmalkimetrical methods is contained in the answers to these questions. Taking our stand upon this we may pass on to consider what is the most suitable variety of indicator, and what is the most suitable variety of tritrating acid to employ in our hæmalkimetrical observations.

Selection of a suitable variety of indicator.—Indicator-acids, like other acids, differ amongst themselves in their *avidity* for bases. Some indicators, and litmus is a good example of such an indicator, are able to withdraw bases, not only from the normal salts of weak acids (e.g., from Na_2CO_3 and Na_3PO_4), but also from certain chemically acid salts (e.g., from $NaHCO_3$ and Na_2HPO_4). Other indicators, such, for instance, as phenolphthalein, are indeed able to withdraw bases from the normal salts of weak acids, but they are quite unable to withdraw bases from any chemically acid salts. It will be manifest on consideration of these facts that when we are testing a fluid which, like the blood, contains chemically acid salts in solution, it will not be a matter of indifference to our results whether we employ litmus or phenolphthalein as our indicator. On the contrary, the results which we obtain with the one variety of indicator will differ, not only quantitatively, but also qualitatively, from those which we obtain with the other variety of indicator. We shall find, for instance, that normal blood is always definitely alkaline to litmus, whereas it is almost always neutral or acid to phenolphthalein. We shall find, in other words, that litmus is always able to withdraw bases from normal blood, whereas phenolphthalein is generally unable to do so. In the light of this fact it will be manifest that when we propose to ourselves to measure the alkalinity of the blood we are in point of fact proposing to ourselves to measure the capacity of the blood for yielding up bases to one particular variety of indicator—to wit, to free (i.e., red) litmus. Our question as to what is the most suitable variety of indicator to employ for hæmalkimetrical purposes is thus in some measure resolved. The most suitable indicator will be a red or neutral tinted litmus paper.[2] We have still to consider the question of the sensitiveness of our indicator.

Selection of a sufficiently sensitive sample of red litmus paper.—It will be obvious to reflection that inasmuch as red litmus is prepared by liberating the litmus acid from its salts by an excess of added acid, ordinary red litmus paper will contain traces of free acid which will seriously interfere with its sensitiveness to the presence of bases. In view of this fact, every litmus paper which is employed in hæmalkimetrical observations ought previously to be tested as to its sensitiveness. A good sample of red or neutral tinted litmus paper ought to show a distinct and immediate colour change when it is dipped into a forty-fold diluted normal human serum.

Selection of a suitable variety of tritrating acid.—It has been customary to employ solutions of organic acids (solutions, for instance, of oxalic, citric, or tartaric acids) for hæmalkimetrical purposes. The employment of these acids presents an undoubted advantage from the point of view of convenience of preparation. For standardised solutions of these acids can in each case be prepared by merely dissolving a weighed quantity of the particular acid in a measured quantity of water. On the other hand, the employment of these solutions of organic acids is open to serious objection, inasmuch as solutions of these organic acids become gradually weaker owing to the breaking down of these acids under the influence either of bacteria or of light and oxygen. We shall avoid this great source of fallacy in our measurements if we employ standardised solutions of sulphuric acid as our tritrating acid. These questions relative to the most suitable indicator and tritrating acid having been satisfactorily resolved we may pass on to consider the methods of dealing with practical difficulties which are associated *first*, with the presence of blood corpuscles in the blood the alkalinity of which we desire to elicit, and, *secondly*, with the necessity of operating with minimal quantities of blood.

Methods of dealing with the difficulties which are associated with the presence of red blood corpuscles in the blood.—Various methods of dealing with these difficulties have been proposed. Liebreich proposed to deal with these difficulties by impregnating slabs of alabaster or porous clay with litmus. The upper surface of these slabs was intended to hold back the red blood corpuscles while the plasma infiltrated into the substance of the slab. It was proposed to bring the colour change which occurred in the litmus into view by washing off the layer of red blood corpuscles which had deposited itself on the surface of the slab. Schäfer proposed to deal with the difficulty in a somewhat similar way. He coated over his litmus paper with a glaze which was designed to hold back all the red blood corpuscles while it remained perfectly permeable to the plasma. Lastly, Landois, Drouin, and others have dealt with the difficulty by diluting the blood with various salts solutions, and by allowing this diluted plasma which was thus obtained to purge itself of its red blood corpuscles by creeping up by capillarity into a strip of test-paper which was hung into the containing vessel. None of these three methods appears to be well adapted to the *quantitative* determination of the alkalinity of the blood, for by none of these methods can we effect that complete separation of the red blood corpuscles from the blood fluid which is absolutely essential to the accurate determination of the neutral point. In addition to being open to objection in this respect, the method which is employed by Landois and Drouin is open to the serious objection that the more the blood is diluted the more difficult does it become to determine the neutral point with accuracy.

Selection of a variety of blood fluid which shall be suitable for hæmalkimetrical observations.—When we take the defects of the above-mentioned methods into consideration we begin to ask ourselves whether it is not permissible to dispense

[1] Consideration will show that these indicators are in reality acid substances which differ from other acid substances only in possessing the property of combining with bases to form distinctively coloured salts.

[2] Blue litmus paper might also be employed as an indicator inasmuch as it would indicate to us the point at which a surplus of tritrating acid has been added to the blood. But the use of blue litmus would be associated with a double disadvantage. In the first place, when blue litmus is employed it is always a matter of some difficulty to distinguish the red colouration which is indicative of a surplus of added acid from the red colouration which is referable to the presence of red blood corpuscles. In the second place, when blue litmus is employed it is difficult to distinguish the fugitive red colouration which is produced by the carbonic acid which is evolved from the blood under the influence of the tritrating acid from the red colouration which is indicative of the presence of an excess of this tritrating acid. It is obvious that both these sources of fallacy are avoided by the employment of a red or neutral tinted litmus.

Digitized by Google

with the immediate separation of the corpuscles from the blood-fluid, and to employ a blood-fluid from which the corpuscles have been separated by more effectual and more leisurely processes. We begin to ask ourselves, in fact, whether we may not employ for alkalimetrical purposes, either the perfectly corpuscle-free plasma, which may be obtained by allowing a decalcified blood to sediment in a capillary tube, or the perfectly corpuscle-free serum, which can be obtained by allowing the serum to exude from an ordinary blood-clot. As a matter of fact, an objection can be raised against the employment of either of these blood fluids. This objection is based upon the fact that the blood undergoes a gradual diminution in alkalinity after it has left the blood-vessels. It might, therefore, be urged that the alkalinity of the sedimented plasma or exuded serum would not be a correct measure of the alkalinity of the circulating blood. But consideration will show that this would not be a fatal objection to the utilisation of serum or sedimented plasma if it could be shown, first, that the serum and plasma ultimately come to a condition of stable equilibrium in the matter of alkalinity, and secondly, that the definitive alkalinity of these blood fluids is a faithful index, or even a tolerably faithful index, of the alkalinity of the intravascular blood. Now it is practically certain that these conditions are actually realised. In the first place observations of Zuntz, Peiper, and Winternitz on the serum, and similar observations of my own on the plasma, have shown that the serum and plasma arrive at a condition of stable equilibrium, within at any rate a few hours, after the blood has been withdrawn from the vessels. And, in the second place, observations of Dronin, which again have been supplemented by a considerable number of observations of my own, have shown that changes in the alkalinity of the circulating blood invariably manifest themselves in charges in the alkalinity of the serum. In view of these facts, and of the fact that it is difficult, if not impossible, to determine with any degree of precision the neutral point of a blood-fluid which contains any red blood corpuscles, it will be obvious that we shall be able to obtain more trustworthy data with reference to the variations in the alkalinity of the blood if we employ, in lieu of the fresh plasma which is contaminated with red blood corpuscles, either the corpuscle-free serum which exudes from a clot or the corpuscle-free plasma which can be obtained by the sedimentation of decalcified blood. Our simplest course—and in these matters the simplest course is always the best course—would appear to be to employ for all hæmalkimetrical purposes the serum which separates out from an ordinary blood clot.

Methods of dealing with the difficulties which are associated with the necessity of operating with minimal quantities of blood-fluid.—The difficulties which are associated with the necessity of operating with minimal quantities of blood-fluid are generally got over by measuring off a series of very small samples of blood fluid into a series of accurately measured, and progressively increasing, quantities of the titrating acid. The principles of this method cannot be improved upon. On the other hand, the procedure which is usually adopted may be improved upon in two particulars. In the first place, it is well, instead of measuring off the blood or blood fluid into many times its volume of the acid solution, to mix the blood fluid with not more than an equal quantity of the acid solution, and so to avoid unduly diluting it. In the second place, it is well in measuring out the required quantities of acid and blood fluid to employ thin-walled capillary pipettes[3] (such as can be made by drawing out a piece of ordinary glass tubing in the flame) instead of the thick-walled capillary pipettes which are made out of thermometer tubing. The advantages which we gain by employing such thin-walled capillary pipettes are the following: (1) we can readily fill in these capillary pipettes by capillary attraction alone; (2) we do not lose any of our fluid by diffusion over the external surface of the pipette[4]; and (3) we can at any moment and without any trouble make and calibrate such pipettes for ourselves instead of having to purchase them from a glass-blower. We have now sufficiently broken the ground, and may, therefore, pass on without further prologue to the description of the practical details of the method which has been foreshadowed above.

PRACTICAL DETAILS OF THE METHOD OF MEASURING THE ALKALINITY OF THE BLOOD.

Preparation of the necessary apparatus.—The necessary apparatus is of the simplest kind. It consists of a couple of glass capsules for receiving the blood which is drawn off from the finger, of one or more capillary pipettes for measuring and mixing the serum with the titrating acid, and of half-a-dozen watch-glasses. The blood capsules and the capillary pipettes[5] are made out by drawing out pieces of ordinary glass tubing (of, say, five-sixteenths of an inch diameter) after heating them in a flame.[6]

Preparation of the necessary reagents.—The necessary reagents consist (*a*) of a supply of a sufficiently sensitive red litmus paper; and (*b*) of a series of dilutions of a standardised sulphuric acid. The preparation of a sufficiently sensitive red litmus paper presents no difficulty if we have at our disposal a satisfactory sample of blue litmus paper, such, for instance, as may be obtained from Grübler and Co., of Leipzig. This blue litmus paper is first to be steeped in a very weak—e.g., in a 1 in 20.000—solution of hydrochloric acid until it assumes a reddish colour. It is then to be carefully washed in distilled water until all traces of fresh acid are removed. Finally, it is to be dried in a hot-air chamber. A litmus paper which is thus prepared will be sensitive enough to respond with an immediate colour change when it is dipped into a twenty- to forty-fold dilution of normal human serum. The weak solutions of standard acids which we require for purposes of titration can be conveniently made by making a series of progressive dilutions of normal sulphuric acid. Five such solutions—to wit, a twenty-, thirty-, forty-, fifty-, and sixty-fold dilution—of normal sulphuric acid will suffice for all ordinary purposes. From these, as will be presently explained, any further dilutions which may be necessary may very easily be prepared.

Method of obtaining blood and serum for hæmalkimetrical purposes.—A sufficient supply of blood can be obtained from a prick in the finger-tip. The most convenient implement to employ for drawing blood is a sharp-pointed steel nib one of whose points has been broken off. Blood in ample quantities can be obtained by twisting a handkerchief round the finger and making pressure from above downwards. The blood which is obtained in this manner is filled into one or two blood capsules. It may either be aspirated into the capsule, or—and this is the easier plan—the blood capsule may be held at a lower level than the drop of blood, and the blood may then be allowed to run in by gravity, aided by capillary attraction. In any case the capsule ought to be filled in in such a manner that one of its ends may remain perfectly free from blood. When the capsule has been filled in, one or both of its ends may be sealed up in the flame. The blood is then to be allowed to clot undisturbed. As soon as the clot has sufficiently retracted and the serum has attained its definitive alkalinity—i.e., after a period of from three to twenty-four hours—both ends of the capsule are broken off and the colourless serum[7] is drawn off by inserting the end of the capillary pipette into the capsule.

Method of performing the titration.—Having obtained our serum, it will be convenient to draw off from the capsule at first only the quantity which will be needed for our first titration. It will be well not to employ for this first titration more than about a sixth of the whole available quantity.

---

[3] The method of making and calibrating these pipettes will be described below.

[4] It will be obvious that this consideration is not of any great importance when, as, for instance, in the case of blood corpuscle estimations, we are measuring off a small quantity of blood into a much larger quantity of diluting fluid. On the other hand, wherever, as here, we are concerned to mix a small quantity of blood with an equally small quantity of a diluting fluid, it is essential to accuracy that we should not lose any of our fluid by its diffusion over the surface of the pipette.

[5] A *blood capsule* consists of a piece of glass tubing which has been heated in two places about half an inch to an inch apart, and which has been drawn out at these places into a capillary tube. A *capillary pipette* consists of a piece of glass tubing which has been heated in one place, and which has been drawn out there into a capillary tube. It is convenient, but it is not essential, to form a mixing chamber upon the capillary pipette by heating and drawing out the tube again at the point where the wide tube begins to tail off into the capillary stem.

[6] If an ordinary blow-pipe flame or a Bunsen flame is not available the glass tubing can, in conformity with a suggestion which was made by Surgeon-Major Semple and myself, be satisfactorily drawn out in the extemporised blow-pipe flame which can be obtained by applying a lighted match to a finely divided spray of methylated spirits.

[7] The serum which is obtained in this manner will, in the large majority of cases, be perfectly free from blood-corpuscles. If, however, it happens to be contaminated with these, it may very easily be freed from them by a simple process of sedimentation. To accomplish this it will only be necessary to seal up the capillary pipette which contains the bloody serum and to set it up on end for a few minutes in a test-tube rack.

Digitized by Google

If the total quantity which is available is a very small quantity we shall therefore employ an extremely fine capillary pipette. If, on the other hand, we have a relatively considerable quantity of serum available we shall employ a capillary pipette of correspondingly larger bore. In any case, we shall do well to arrange matters so that the quantity of serum which we have at disposal for our first tritration shall occupy not less than 1–2 cm. of the stem of our capillary pipette. We may assume for the sake of fixing our ideas that it occupies a length of exactly 2 cm. In such a case we make a mark with a red wax pencil upon the stem of the pipette at a point about 2½ cm. above the end of the pipette. Having done this, we turn up the point of the pipette and allow the serum to run down the stem of the pipette up to the point which is indicated by the red pencil mark. The object of this manœuvre is to take an air-bubble index into the point of the pipette. Having done this, we proceed to dip the end of the capillary pipette into a drop of our twenty-fold dilution of normal sulphuric acid, and we allow the acid to run up into the stem of the pipette until the upper margin of the air-bubble which separates the serum from the acid just reaches the red mark upon the stem of our pipette. It is obvious that when the air-bubble index reaches this point the quantity of acid solution which has been run up into the stem of the pipette will be exactly equivalent to the amount of serum which was drawn off into the pipette. Having thus obtained exactly equal quantities of our serum and our tritrating acid, our next step will be to mix the contents of our capillary pipette. We can do this either by drawing up the contents of our capillary tubes two or three times through our mixing chamber, or, if our tube is unprovided with a mixing chamber, by blowing out the contents of our capillary pipette into a clean watch-glass and then re-aspirating them, after complete mixture has been effected, into our pipette. Mixture of the contents of our pipette, having been accomplished, we have only to blow out the mixture of serum and tritrating acid in a series of separate drops on to the surface of a strip of our red litmus paper. In the case of the particular mixture we are considering—i.e., in the case of a mixture consisting of equal volumes of serum and a twenty-fold diluted normal sulphuric acid—we should almost certainly find that we had in our mixture an excess of acid. We should then proceed in a precisely similar manner to tritrate with each other equal volumes of serum and a thirty-fold diluted normal acid. If we were dealing with normal blood this mixture might or might not have a slightly acid reaction. If this mixture proved to be still acid we should of course proceed to test equal volumes of serum and a forty-fold diluted normal acid. This mixture would, in the case of normal blood, almost to a certainty be alkaline. Supposing that it was alkaline, and that the reaction of the mixture of equal volumes of serum and thirty-fold diluted acid had proved to be acid, we should then proceed to mix in a clean watch-glass equal volumes of a thirty- and a forty-fold diluted normal acid. We should tritrate our serum again with this thirty-five-fold diluted normal acid. If we found that this quantity of acid just sufficed to neutralise the acidity of our sample of serum, it is obvious that the alkalinity of our serum would be most simply expressed by the fraction $\frac{N}{35}$. For a serum which is exactly neutralised by an equal volume of a thirty-five-fold diluted normal acid would obviously correspond in alkalinity to a thirty-five-fold diluted normal solution of alkali.

In a future communication I hope to draw attention to some results of therapeutic and diagnostic importance which have been obtained by the exploitation of this method of measuring the alkalinity of the blood. For the present it will suffice to put on record for the guidance of others who may be disposed to employ this method of measuring the alkalinity of the blood that the maximum value which has been found by this method for the alkalinity of the normal serum has been $\frac{N}{25}$. This result has been obtained only once. In the case of thirteen other normal persons the serum has been found to possess an alkalinity which has always varied between the values of $\frac{N}{30}$ and $\frac{N}{45}$. On the average the alkalinity of the serum has been equivalent to about $\frac{N}{35}$.

ROYAL FREE HOSPITAL.

A CASE OF DILATATION OF THE STOMACH ASSOCIATED WITH PERIPHERAL NEURITIS.

(Under the care of Dr. WALTER CARR.)

A MAN, aged twenty-eight years, was admitted into the Royal Free Hospital on Nov. 20th, 1896. He said that since he was about sixteen years old he had been subject to occasional attacks of abdominal pain, lasting about twelve hours and not specially related to food. For some years these attacks were not attended by sickness, and the symptoms from which he suffered do nct suggest that he had a gastric ulcer; neither had he ever swallowed any corrosive fluid. Since 1890 the attacks of pain had recurred about every two months, had been more severe, and had been terminated by copious vomiting. Since about Christmas, 1895, they had become much more frequent, sometimes occurring two or three times a week, with very severe pain; exertion seemed to increase their frequency. The patient said that before the attacks his stomach felt very uncomfortable and he could feel it "working" (evidently the peristaltic movements). After the sickness he was much relieved for a time. In June, 1896, his legs had begun to get weak, with much pain in the calf muscles, numbness and tingling in the legs and slightly in the hands; since August he had been unable to walk and had wasted rapidly. No history was obtained of any acute illness except influenza five years ago. He entirely denied any alcoholic excess, saying that he had rarely taken more than one or two glasses of beer a day. On admission the patient was seen to be a well-built man, about 5 ft. 11 in. in height, but greatly emaciated; his weight was 9 st. 7 lb. He had not been sick for a week, but the day after admission he brought up 7½ pints, and vomited from 1 pint to 2½ pints nearly every day for the next week; he also brought up much flatus. The vomit contained abundant sarcinæ, but no blood. The tongue was clean, the appetite fairly good, and the bowels acted nearly every day. On examination of the abdomen peristalsis was frequently visible, starting in the left hypochondrium and passing across the umbilical region to the right. On palpation no tumour, thickening, or resistance could be detected in the neighbourhood of the pylorus or elsewhere. The stomach was distended by giving bicarbonate of potassium and citric acid, and was found to be greatly dilated, reaching well below the umbilicus, though the exact limits could not be defined. The liver dulness was normal. In regard to the nervous system there was no complete paralysis of any limb, but his legs were very weak, especially the left, and he was unable to extend the left toes. He could only walk very feebly, requiring a great deal of support. He could just stand alone, but not when the eyes were shut. No other evidence of ataxy was detected. All the muscles of the legs were much wasted. In the upper limbs wasting was especially marked in the supra- and infra-spinati and the interossei. In the muscles below the knees no reaction was obtained to faradaism, but all the muscles reacted to the galvanic current. He complained of tingling and numbness in the legs, and the calf muscles were very tender. There was very slight impairment of sensibility below the knees, chiefly about the feet. No girdle sensation was present. The knee-jerks and plantar reflexes were absent. There was no loss of sexual power or of control over the sphincters. His pupils were normal and no ophthalmoscopic changes were found. His chest was healthy. The temperature was normal throughout his stay in the hospital. The urine contained no albumin or sugar.

The patient was kept in bed and carefully dieted; he was given hot water to drink before each meal, little or no fluid being allowed with the food; strychnine

Digitized by Google

was given by the mouth. From Nov. 28th the stomach was washed out every morning, at first with simple warm water and afterwards with a solution of bicarbonate of sodium (two grains to the ounce), which seemed to act rather more beneficially. At first a large quantity of very offensive sour-smelling mucus and grumous material was brought away, but this rapidly diminished, and after a few weeks the washings each day returned quite clear. The effect of the treatment was immediate, the vomiting ceased after the first washing, only recurring occasionally afterwards, chiefly when the patient began to get up, movement seeming at first to excite it. The appetite improved, the flatulence diminished, and he began to gain weight. The nervous symptoms also steadily improved, the legs got stronger, so that the patient began to walk alone, sensation became normal, and the tenderness of the calf muscles slowly subsided. He was discharged on March 7, 1897, greatly improved in every respect and having gained 18 lb. in weight. He was seldom sick, and his appetite was good; there was still some flatulence, but much less than before. He could walk well and all the nervous symptoms had disappeared, except that there was still some weakness of the extensors of the left toes and the knee-jerks had not returned. He had learned to wash out his stomach himself without any difficulty and was directed to do so every morning before breakfast. He was seen on May 3rd and had then not been sick for six weeks; he was feeling well and much stronger; he could move all the toes quite freely; the knee-jerks were still absent; his weight was 11 st. 4 lb., a further gain of 7 lb. since leaving the hospital.

Remarks by Dr. WALTER CARR.—The above case presents several features of interest. The diagnosis of dilated stomach was obvious from the quantity and characters of the vomit as well as from the examination of the abdomen. Its causation, however, is obscure. The marked visible peristalsis, indicating hypertrophy of the muscular coat, points doubtless to the existence of definite obstruction at the pylorus, and hence mere chronic catarrh as a possible cause of the dilatation is probably excluded, even were it at all likely to lead to such great enlargement in a young and previously very robust man leading an outdoor life. All the ordinary causes of pyloric obstruction can also with reasonable confidence be excluded; there is nothing to suggest that there has ever been any peritonitis leading to displacement or narrowing of the pylorus; malignant disease is, of course, out of the question; a gastric ulcer near the pylorus might no doubt have led in healing to narrowing of the orifice, but the patient's early gastric symptoms, so far as he remembers them, were not suggestive of ulceration, which is, moreover, exceedingly improbable in an otherwise healthy lad of sixteen, at or before which age abdominal pain, without any vomiting, was first complained of. It is well known that when gastric dilatation occurs in comparatively early life the cause is often obscure, and I think that in this, as in some other similar recorded cases, a congenital obstruction or kink at the pylorus may possibly be present. The narrowing is probably but slight, and consequently symptoms only arose slowly, some hypertrophy of the muscular coat being sufficient for a long while to overcome the obstruction; but as soon as food began to be retained for a considerable time fermentation would occur, and the gases evolved, by distending the stomach, would lead to more rapid increase in the dilatation and so to the development of the characteristic symptoms. Some such theory as this best explains, I think, the commencement of gastric symptoms in early life, the gradual but steady increase in their severity, and the very great dilatation ultimately attained. There is no need to emphasize the excellent results of the treatment by lavage; improvement began after the first washing, and all kinds of medicinal and dietetic treatment had been tried previously without the slightest benefit. If there be permanent pyloric obstruction the washing out will doubtless have to be continued for an indefinite time, but this is not a serious matter, as the patient seems rather to enjoy it than otherwise.

As to the nervous symptoms, the partial but symmetrical affection of both motion and sensation, the tenderness of the muscles, the loss of the knee-jerks, together with the absence of girdle pain or of any affection of the sphincters or pupils, presented a sufficiently characteristic picture of peripheral neuritis, a diagnosis confirmed by the complete recovery. The chief interest of the case, however, centres in the causation of this neuritis; undoubtedly, the symptoms strongly suggest the alcoholic variety, but the patient's appearance and his behaviour whilst in hospital certainly did not point to any alcoholic excess, and I see no reason for doubting his statement that he rarely took more than a glass or two of beer a day. In this opinion his regular medical attendant (Mr. Greeves, of Willesden), under whose care he had been for a long time, entirely coincides. The patient had not suffered from any of the acute specific fevers, nor had he been exposed to any other probable cause of multiple neuritis so far as could be ascertained; and from the way in which the nervous symptoms developed as the gastric troubles increased, and began to improve as soon as the stomach was washed out, I am disposed to attribute the neuritis to absorption of the products of bacterial fermentation from the greatly dilated stomach. There seems nothing improbable in this view, although I am not aware of any previous cases having been recorded. For a long period, probably some years, large quantities of toxic substances must have been formed in the stomach, and some would doubtless be absorbed; and there seems no reason why they should not exercise a special action on the nervous system similar to that of the many poisons, organic and inorganic, which are recognised as possible causes of multiple neuritis. Of course, it may be argued that if the neuritis arose from this cause other similar cases ought by this time to have been recorded; but be it remembered, in the first place, that excessive dilatation of the stomach, persisting for any considerable time, is by no means a common condition (the most frequent cause of great dilatation is probably pyloric cancer, and this is necessarily fatal in a comparatively short period); and secondly, that alcohol and the toxins of the acute specific fevers (except diphtheria) cause multiple neuritis in only a very small minority of the cases in which they are present, and that similarly the poisons generated in a dilated stomach may only attack the nerves in an extremely small percentage of cases. Dr. Henry Waldo, of Bristol, has recorded [1] a case of peripheral neuritis in a girl, aged twenty-one years, following upon symptoms of poisoning after eating tinned salmon. He attributed the neuritis to the salmon and not to any metal. If this conclusion be correct, there seems no reason to suppose that if the products of decomposition of food outside the body can lead to neuritis, those formed as a result of its retention in the stomach should not at times exercise a similar action.

MELBOURNE HOSPITAL.

A CASE OF RUPTURE OF THE LIVER; OPERATION; RECOVERY.

(Under the care of Dr. W. MOORE.)

IN the less severe ruptures of the liver, which are not accompanied by such an amount of hæmorrhage as to prove rapidly fatal, collections of blood and bile tend to form, and should the laceration of the organ have been on its upper surface, adhesions between the liver and the anterior abdominal wall may so shut in the effused fluids that the general peritoneal cavity escapes. The implication of the right pleural cavity is by no means unusual in the partial ruptures of the upper surface of the liver. A case in many respects similar to the one recorded below was brought before the West London Medico-Chirurgical Society [2] by Mr. W. H. Battle in 1894.

A boy, aged eleven years, was admitted into the Melbourne Hospital under the care of Dr. W. Moore on May 31st, 1897. The patient had been kicked by a horse on the right side—the lower part of the (lateral) thorax—two days prior to admission. He was seen soon after the accident by a medical man, who found him completely collapsed and complaining of great pain in the right side; the diagnosis made was rupture of the liver. In four or five hours after the accident the abdomen had become distended, and this condition lasted about five days, but during these five days there were no other marked symptoms; the bowels acted after enemata. Four days prior to admission vomiting set in and had since continued. It was on account of this condition that he was sent to the hospital, as the medical attendant thought that the vomiting was due to

[1] Brit. Med. Jour., vol. i., 1889, p. 589.

Digitized by Google

pressure on the duodenum or pyloric end of the stomach, and that an operation might be required. The vomited matter was always fluid and of a greenish colour, with specks of blood in it. The bowels had not acted for four days in spite of the administration of enemata and of purgatives. The patient suffered from pain at times, which appeared to come on in spasms. There was no pain at the time of admission. On examination the patient was found to be a pale, thin boy. His temperature was 98 6° F. and the pulse was 110, of small volume, and easily compressible. He lay on his back with his knees drawn up. There was no abdominal distension, but there was some fulness in the hepatic region, and the liver dulness was increased. On percussion there was marked tenderness over the liver. He was kept in bed, and hot fomentations were applied over the upper part of the abdomen. For some days the boy presented no symptoms of importance. The vomiting ceased, his bowels acted, and the temperature was normal. But on June 6th it was noticed that his respirations were much quickened, and on examination it was found that there was a large rounded swelling below the ribs and just to the right of the mid-line; the liver dulness was greatly increased, and there was dulness over the right side almost up to the clavicle; the abdomen was somewhat distended and tympanitic. Two days later these conditions were slightly more marked, but it was noticed that the liver dulness was little increased downwards in the mid-axillary line. The temperature was slightly raised. On the 8th the chest was aspirated in the sixth right interspace, and twenty-four ounces of yellowish green (bile-stained) fluid were drawn off. This fluid was subsequently found to contain bile. The chest at once became resonant on the front and in the axilla. The prominence in the epigastrium became slightly less. During the next two days there was no improvement in the patient's condition; his pulse was quick, feeble, and irregular; he was very pale, and in the epigastrium, a little to the right of the mid-line, the rounded swelling had become very prominent and distinct. The margin of the liver could be felt about two inches above the umbilicus. His abdomen became greatly distended all over and tympanitic except in the epigastric and right hypochondriac regions. At this time he generally lay with his knees drawn up. On the 10th, under chloroform, Dr. Moore made a three-inch vertical incision through the rectus muscle a little to the right of the mid-line, commencing just below the ribs. The parietal peritoneum appeared to be much thickened, and on opening it a cavity containing a large quantity of dark fluid, in which clotted blood and bile could be easily distinguished, was entered. This cavity was very large, at least six inches deep, and it extended upwards towards the diaphragm. The upper convex surface of the liver could be felt forming its lower boundary, and it was shut off from the general peritoneum by adhesion of the liver to the anterior abdominal wall. The cavity was washed out with warm boracic acid lotion and drained with strips of iodoform gauze. Four horsehair sutures were used to close the ends of the incision. The wound was dressed with dry antiseptic dressings. Even after this the boy's condition was not satisfactory. The discharge from the wound quickly diminished, and in a few days almost ceased. The temperature was slightly raised, there was no increase of dulness in the front of the chest or in the axillary region, but the epigastric fulness was well marked, and now it appeared to fluctuate distinctly. On the 16th a hypodermic needle was introduced through the wound and a little thin, dark, bile-like fluid was drawn off. Just before he was taken to the operating room on the following day he was seized with vomiting and his temperature rose to 103 6°. He was anæsthetised, and a trocar and cannula were introduced through the wound into the fluctuating swelling in the epigastrium, and dark fluid bile flowed through the cannula. The cannula was removed and a forceps was introduced, opened, and withdrawn to enlarge the opening; in this way a very large quantity, probably several pints, of fluid was evacuated. A large rubber drain-tube was introduced and left in. From this time the patient rapidly improved; he became less pale, his breathing was easier, and the fulness in the epigastrium disappeared. The discharge of bile was very profuse for about a week; the tube was removed on the 22nd; on the 27th the discharge was much less and he was allowed to be up. By July 5th the discharge had ceased altogether and the boy left the hospital.

Remarks by Dr. MOORE.—In this case it is evident that the kick caused a rupture of the liver on to its upper (diaphragmatic) surface; through this rupture bile and blood were slowly effused, but they were shut off from the peritoneum by adhesions, which developed rapidly before the effusion had become great in amount. The wound on the surface of the liver healed, but a cavity was left in the substance of the organ into which the torn bile-ducts poured their contents. Some of the bile that had escaped through the tear in the surface of the liver found its way through the diaphragm into the right pleura and gave rise to a pleurisy with effusion. There were thus three separate collections of fluid—viz., in the right pleura, in a space formed between the diaphragm, the convex surface of the liver, and the anterior abdominal wall; this commenced to form immediately after the accident, and probably did not increase in amount after the first twenty-four hours; and, lastly, in a cavity within the liver; this last collection no doubt went on slowly increasing until it was evacuated. In the *Australian Medical Journal* for 1891 a somewhat similar case is briefly recorded by the writer. "A man, aged thirty-three years, was admitted into hospital on April 30th, 1891, having been crushed between two lorries. He complained of abdominal pain and tenderness, particularly over the liver. There was an abrasion of the abdomen between the ribs and the ilium on the right side and another just below the angle of the scapula on the left side. The pain was not very severe; his pulse was not quickened; flatus passed by the bowel during the next three days. On May 3rd he was attacked with vomiting, his skin became sallow, not jaundiced, and the liver dulness was found to extend to the crest of the ilium. His bowels were open after enemata, but the character of the motions was not noted. The following day his temperature was 99 8°, this being its first rise. On May 7th his temperature was 101°, and the pain was much more severe. From this time the dulness below the liver gradually diminished, whilst dulness began to extend gradually upwards over the chest on the right side until it reached the clavicle. For some days the patient refused to have anything done. On May 20th I aspirated in the mid-axillary line between the fifth and sixth ribs, and drew off forty ounces of dark-coloured bile. On May 23rd twenty-eight ounces of similar fluid were withdrawn. The breathing gradually improved and the dulness diminished. The patient was discharged on June 22nd with some impairment of mobility of the right side of the chest. Here there must have been a partial rupture of the liver; the torn bile-ducts poured their contents into the cavity thus formed; this cavity gradually increased in size and finally burst, probably by a very small opening through the diaphragm."

Reviews and Notices of Books.

The History of Intellectual Development on the Lines of Modern Evolution. By JOHN BEATTIE CROZIER. Vol. I. London: Longmans, Green, and Co. 1897.

DR. BEATTIE CROZIER, whose previous treatise, "Civilisation and Progress," met with a reception some few years ago that is but rarely accorded to works of philosophy, has now given to the public in his new book an expansion of one side of this great theme. In "Civilisation and Progress" he contented himself with setting out in a general way the parts played in the complex movement of civilisation by the cardinal factors of religion, government, science, and material and social conditions, and to pointing out the laws which regulate the interplay of these factors—a fairly large programme, but students of philosophy well remember how thoroughly and yet how simply it was carried out. In the volume now before us, and in those volumes projected by the author to follow it, he proposes to apply the general principles he has already laid down in "Civilisation and Progress" to the detailed consideration of one great feature in that civilisation—namely, intellectual development. Under this term he includes religion, science, and philosophy, and the purport of his work is to show that the human history of these three departments of intellectual development can be shown to

Digitized by Google

follow scientific laws. In other words, Dr. Beattie Crozier will attempt to prove, and is convinced while so doing of the possibility of proving, that the views held by, for example, Plato, Aristotle, Buddha, and St. Paul could have been anticipated; that their teachings on the great problems of human life were not only such as they were likely to hold, having regard to their environment rather than their individuality, but were such as in accordance with definite though still undiscovered laws they must have held.

To the execution of his heavy task the author brings certain important qualities likely to ensure success. He has learning, eloquence, and humour, so that he is able to instruct us by his comprehensive surveys of the history of the supreme intellectual movements of the world, and at the same time to hold our attention for long spells—a most important thing in a book of reasoning—and to drive home his teaching by some apt allusion or homely simile which stays by us, and epitomises for us many pages of solid argument or exhaustive reference. Here, for instance, is a happy allusion to the philosophy of Hegel, who may be said to have held with Kant that an assertion can be at the same time true and false, and that the opponent who was contradicting him might be equally in possession of truth with himself. Of this vague and illusory philosophy Dr. Crozier says: "Although his [Hegel's] law was in my judgment the true law of the movements of intelligence in the abstract, it was, nevertheless, like a hat too big for the head, altogether too wide and general to be of any scientific value for determining the line of evolution of the lesser divisions of intellectual development, except, perhaps, in relation to German metaphysics, from which, indeed, the law was derived, and to which it is specially applicable; in the same way as the general law of evolution, although, doubtless, true in itself, is much too wide to be offered as a serious explanation of the special phenomena of the Stock Exchange." Nor do the qualities we have mentioned alone recommend Dr. Crozier's work to our notice. In addition, he has employed a very sound and modest plan. In his materials he has gone direct to the original authorities living at or about the time of the events recorded, and then, with the object of "repairing the gaps and oversights inevitable in the view taken of any large and complex subject by a single mind," has had recourse to those great modern authorities who themselves drew from the original fountain heads, in particular to the works of those who have devoted themselves to the elucidation of some single historic period or school of thought and to the authentic lives of men who have made epochs in the story of civilisation. This is the model way to present obscure and difficult themes, particularly themes the consideration of which will necessarily occupy much time. Seeing the whole subject through the author's eyes the reader obtains a comprehensive grasp of it, benefiting by the uniformity of treatment which one mind, if logical, would necessarily use in dealing with similar historical events, whatever their date, origin, or issue. The good of specialism is in this way retained and the ill rejected. At the same time the authorities quoted by the author in his support or criticised by him in defence of any departures from their teachings, can be examined by the reader for himself. He is not asked to follow any lead blindly. Such and such are the deductions made by the author. Are they correct in view of what more special workers have to say? If they are not, have the authorities blundered or has the author misinterpreted them?

The present instalment of Dr. Crozier's work covers a consideration of the evolution of Greek and Hindoo thought, of Judaism, and of the evolution of Christianity. He treats all four sections dispassionately, and gives to each impartially what he considers to be its proper importance in the scheme of intellectual development. The story of the evolution of Christianity is in length equal to the stories of the other three put together, although we are only taken as far as the end of the second century; but this is intelligible if only because much of the work that still lies ahead of the author is necessarily a continuous narrative of the Christian religion, while the influences of the Greek, the Hindoo, and the Jew are for all practical purposes over and done with. To what extent Dr. Crozier has performed the task that he has set himself—viz., the complete application of the theories of evolution to the intellectual development of the human race—we leave to the judgment of our readers. We have said plainly what we think of his qualities for the due performance of the work and of the spirit in which he has approached it, but it is to the minds of individual readers that he appeals. To some he will appear more convincing than to others, while many may desire to reserve their opinion until the author has written of Mediæval Catholicism, the Renaissance of Learning, the Reformation and the Doctrines of Modern Science, to mention some of the sections which remain to be dealt with. And this last is our own position. Until these important landmarks in the survey of the world's progressive wisdom have been considered by Dr. Crozier, their importance estimated, and their results traced, it is not possible to say how far he has accomplished his intention—that is to say, how far he has been able to show the existence of a law comparable to a scientific law governing the thoughts of men and dictating creeds and their schisms, philosophies and their accompanying facts and fallacies. Criticism at this stage would hardly be fair, as the author may be intending by something he has yet to say to repair what now might seem to be oversights in the presentment of his large and complex labour. An obvious inconsistency may, for example, be found in this volume which will probably be accounted for later, being doubtless an inconsistency in phraseology and not in thought. The author, while designing, as we understand him, to explain or account for the progress of intellectual development in accordance with more or less logical rules—while, that is, applying the general principles by which civilisation has progressed to the detailed evolution of one great factor of that civilisation—imports into his philosophy a coördinating power of unknown force and incomprehensible energy "which is not ourselves and which makes steadily for moral ends," and which directs by "its overarching supernaturalism everywhere enfolding and pervading the world and its affairs" every step that is taken by poor belated man. That we are under such direction is the happy belief of all the devout whatever their creed and of most who lead lives of thought and introspection; but it would almost seem that Dr. Crozier, by admitting the presence of this mysterious force into his calculations, has made it impossible for himself to explain the very problems to unravel which his book has been written. For if he allows himself to be helped in his explanations by falling back upon a First Cause of which he knows nothing, however implicit may be his private trust in its unlimited power, we can always ask him to tell us exactly which episodes in his story are consequential one to the other—the inevitable result of cause and effect working according to definite law—and which must be set down to the caprice of the supreme and unknown X.

Dr. Crozier has written an excellent book. He deals with his great subject lucidly and modestly, with no priggishness or unnecessary display of erudition, and with no slipshod uncertainty of expression. All can read him, and it is not his fault if all cannot understand every word he has written. He has our hearty congratulations on his work as far as it has gone.

Twentieth Century Practice: an International Encyclopædia of Modern Medical Science by Leading Authorities of Europe and America. Edited by THOMAS L. STEDMAN, M.D. Volume VIII., *Diseases of the Digestive Organs.* 1897. London: Sampson, Low, Marston, and Co. Pp. 667.

THIS vast publication has now reached the eighth volume; and twelve more are yet to come, and if all the volumes are as complete in their respective subjects as the one now under consideration the work will be a library in itself.

The first article is under the joint names of Dr. Johann Mikulicz, Professor of Surgery at the University of Breslau, and Dr. Werner Kümmel, also of the same university. The subject is Diseases of the Mouth. After a short introduction, containing the anatomy of that region, good accounts are given of the "general symptomatology" and "special pathology" of affections of the mouth. We then find a description of some of the injuries to which the mouth is liable, including burns. The various diseases of the mouth are then considered, chiefly under the headings of Latin names, such as stomatitis simplex, ulcerosa, and aphthosa. Rare conditions are also described, such as scleroderma and actinomycosis.

Diseases of the Œsophagus are described by Dr. Reginald H. Fitz, of Boston. With the exception of tumours of the œsophagus this is a difficult subject to write upon, but Dr. Fitz has produced an interesting and instructive article.

Dr. Einhorn, Instructor in Clinical Medicine at the New York Post-Graduate Medical School, contributes a long article on Diseases of the Stomach, occupying 250 pages; it really forms a valuable monograph on the subject. Here, again, we notice Græco-Latin terminology freely employed; some of the names will, we think, be new to English readers, such as "hyperchlorhydria" (hyperacidity), "gastrosuccorrhœa continua periodica," and "gastrosuccorrhœa continua chronica." By the first term is understood "an affection which is characterised by a constant secretion of gastric juice giving rise to spells of vomiting and severe pains," and by the second term a condition in which there is a constant secretion of gastric juice even when there is no food whatever in the stomach. A diagnosis of either complaint can only be made with certainty by a repeated examination of the stomach in the fasting condition by means of the tube. Another condition described is "achylia gastrica" or "atrophy of the stomach," a condition in which there is a persistent absence of gastric secretion. Again, in order to diagnose this condition the patients have frequently to undergo the unpleasant operations of the passage of the stomach tube. Next we are confronted with the term "ischochymia," or "a condition in which the stomach is never found empty between meals, but always contains some food, even in the fasting condition." Here, again, "this condition is best recognised by the examination of the stomach by means of the tube when fasting." In our opinion an unnecessary burden would be thrown on the physicians in the out-patient rooms of our hospitals if diagnosis had always to be made by means of the stomach tube. As it is, we prefer to ask our patients certain questions as to the relation between pain and food as regards to time, and the presence or absence of vomiting, &c., and then, according to their replies, we write our diagnosis. This may not be so scientific, but it is certainly more practical, and as regards treatment the patient is just as well off. In reading through Dr. Einhorn's paper we stumble across such terms as "acoria," sometimes spelt with a "c" and sometimes with a "k," "polyphagia," "parorexia," "vomitus nervosus," "pneumatosis," "hypanakinesis ventriculi," "hyperanakinesis ventriculi," "tormina ventriculi nervosa," &c. Dr. Einhorn's paper, in addition to being a most elaborate disquisition on the diseases of which it treats, is also a remarkable study in medical nomenclature. Elaborate directions are given for the examination of the stomach by means of various forms of apparatus, especially Einhorn's "gastrodiaphane," "stomach bucket set," and "gastrograph." Truly, the physician of the future will have his pockets full if he carries about all his modern apparatus. Reviewing this article as a whole, we must give all due praise to the thorough manner in which each gastric disorder is described. It contains a large amount of original work and terminates with a copious bibliography.

The article on Diseases of the Pancreas is by Dr. Hans Levi, Professor of Internal Medicine at the University of Bonn. In his introduction the author points out that our knowledge of diseases of the pancreas is of recent date owing to the comparative rarity of these diseases, to the hidden situation of the organ, and to the fact that we have hitherto had a not very exact knowledge of the functions of the gland. The methods employed for the diagnosis of pancreatic disease are well described, and a fair summary is given of the diseases of the organ so far as we are acquainted with them.

Diseases of the Peritoneum are described by Dr. Farquhar Curtis, Professor of Clinical Surgery, New York Post-graduate School. The embryology, anatomy, and physiology are all considered at length, and then the diseases are taken in the following order: peritonitis, appendicitis, perforation of the stomach and intestine, peritonitis originating from the female generative organs, subphrenic abscess, tuberculous peritonitis, ascites, and tumours. Especially good is the section on appendicitis, the anatomy of the appendix being very complete. Dr. Curtis has produced a most useful paper, which adds considerable value to the publication as a whole.

The article on Animal Parasites and the Diseases Caused by Them is written by Dr. D. J. C. Huber, of Memmingen, Bavaria. Dr. Huber's writings on this subject are well known, and a better author for this subject could not have been chosen. The descriptions of the parasites are lucid and the illustrations well executed.

Treatment of the Diseases Caused by Animal Parasites is from the pen of Dr. James M. French, Lecturer on Morbid Anatomy and Demonstrator of Pathology at the Medical College of Ohio, and contains much useful information.

LIBRARY TABLE.

Dangerous Infectious Diseases. By FRANCIS VACHER, Medical Officer of Health of Cheshire. Reprinted from the *Sanitary Record.* (London: The Sanitary Publishing Company, Limited. Price 1*s.* 6*d.*)—This little book is a reprint of a series of articles originally intended for the use of newly appointed medical officers of health, and also, we should say, from the simple style of its matter, to aid heads of households in the early recognition of an infectious fever so that they may call in medical assistance as soon as possible. The grouping of the different fevers is, as the author admits, quite unscientific, they being classed according to the generally recognised length of the incubation period. It will easily be seen, however, that this method of classification may in many cases be very useful. The question of treatment other than preventive does not come within the scope of this book, but the directions as to disinfection and the probable sources of infection of diphtheria and enteric fever are clearly set out. We would suggest one slight amendment, and that to mention that the papules in small-pox appear on the backs of the wrists quite as soon as, if not sooner than, on the face (vide p. 6).

The Blight of Respectability. London: The University Press, Limited. Price 2*s.* 6*d.*—This book is a rather amusing if not very well written diatribe against things as they are.

Digitized by Google

The author's great *bête noir* is what he calls "respectability," i.e., what the majority of people do and think, and as an instance he quotes the case of the woman mortally wounded in a railway accident who with her dying breath asked the surgeon to put her bonnet straight. Vanity of this sort is nothing new, however, for we all remember Pope's Narcissa, who wished to be rouged when dying. There are grains of wheat among the chaff. Witness the following: "There was a time when trade meant a handicraft; now it is a term for gambling with articles made by ill-rewarded workers." This, we fear, is in many cases true, and due to the craze for cheapness.

JOURNALS AND REVIEWS.

The Journal of State Medicine. London: Baillière, Tindall, and Cox.—The official organ of the Royal Institute of Public Health for September opens with the third of Dr. G. Sims Woodhead's Harben Lectures. A paper read at the Congress of the British Institute of Public Health in Glasgow by Mr. William Mitchell, vice-chairman of the School Board of Glasgow, in which he enters a plea for improved dwellings and improved social conditions for poor children, will be read with interest. To a want of proper housing for children and the nature of their environment the author attributes the unsatisfactory results of School Board work, which is "not at all commensurate with its scope and intention and with the expense and labour and care that are lavished upon it." Finally, the author commends the preamble set forth by our forefathers more than 300 years ago in the education scheme of 1560: "Of necessitie it is that your honours be most cairful for the virtuous education and godlie upbringing of the youth of this realm."

The Quarterly Journal of Microscopical Science. Vol. XL Part 2. August, 1897. Edited by Professor E. RAY LANKESTER, Professor ADAM SEDGWICK, and Professor W. WELDON. London: J. & A. Churchill. Price 10*s.*—This part contains six articles:—1. The Adhesive Tentacles of Nautilus, with some notes on its Pericardium and Spermatophores, by Arthur Willey, D.Sc., with a plate. The cylindriform tentacles are shown to form firm adhesions by their surfaces, not by their tips. The spermatophore sac is at the base of the buccal cone. The author gives a tribute of praise to the precision of the late Professor Huxley's description of the pericardial region. 2. On Some Modifications of Structure subservient to Respiration in Decapod Crustacea which burrow in Sand, with Some Remarks on the Utility of Specific Characters in the Genus Calappa and the Description of a New Species of Albunea, by Walter Garstang, M.A., Oxford, with three very beautifully executed plates. 3. Note on the Anatomy of Sternaspis, by Edwin S. Goodrich, B.A., of Oxford, with two plates. The text gives an account of various internal organs of this Polychæte worm, which are illustrated by numerous figures. 4. On the Relation of the Arthropod head to the Annelid Prostomium, by Edwin S. Goodrich, B.A. This is an article that will prove of great service to those who are working at the morphology of the Invertebrata. There are many illustrations. 5. On the Development of the Californian Hagfish, Bdellostoma Stouti, Lockington, by Bashford Dean, Ph.D, Columbia College, New York, with a plate. In this article it is shown that the Myxinoid differs widely from all other chordates in its developmental type. He claims for it, on developmental grounds, a high antiquity. 6. On the Diplochorda, by A. T. Masterman, B.A., B.Sc., St. Andrews, N.B., with nine plates. An account is here given of the structure of Actinotrocha and of Cephalodiscus.

Liverpool Medico-Chirurgical Journal.—The number for the current half year contains the Transactions of the Liverpool Medical Institution from Jan. 28th to April 22nd, many reviews of books, and nine original articles. Dr. J. Wiglesworth, superintendent of the Lancashire County Asylum at Rainhill, describes two cases of Porencephaly. Both patients were male epileptics. In the first, who was thirty years old at the time of death, the right cerebral hemisphere was congested but otherwise normal; in the left hemisphere there was a considerable loss of substance in the region occupying the upper part of the ascending limb of the Sylvian fissure. The other patient was an idiot of a very low type, and died from phthisis in his twenty-first year; the cerebral substance had almost disappeared over the posterior two-thirds of the brain. Mr. F. T. Paul publishes a successful case of Gastrostomy by Frank's method. In the result the patient, who was a woman, forty-two years of age, suffering from stricture of the œsophagus, looked forward to her meals and her cup of tea with as much relish as the other patients, or even more.

Scottish Medical and Surgical Journal.—Dr. William Stewart, surgeon to Leith Hospital, describes a case of Epileptiform Convulsions and Hemianopsia due to unilateral hydrocephalus and treated by drainage of the lateral ventricle. The patient was a man twenty years of age. He first complained of defective vision in 1888 and had his first epileptic fit in April, 1894. The operation was performed on Oct. 1st, 1896. On incising the cerebral tissue a large cavity was opened, from which much fluid, having all the appearances of cerebro-spinal fluid, escaped. A small indiarubber drainage-tube was introduced and retained till the eleventh day. The wound being soundly healed, and the patient having had no fits, he was discharged on Nov. 24th, seven weeks after the operation. The fits having recurred on April 7th, six months after the operation, the old flap was reflected on April 22nd, a drainage tube introduced, and retained till June 13th; on June 16th the wound was firmly healed. Dr. William Russell, the editor, writes on Migraine and Allied Epileptoid Conditions. Dr. Norman Walker contributes a clinical lecture on the Common Fungus Diseases of the Skin.

Edinburgh Medical Journal.—Dr. T. Myles, surgeon to the Richmond Hospital, Dublin, publishes several cases of Nephrectomy and Nephro-lithotomy, together with an account of Experiments with the Roentgen Rays in the diagnosis of renal calculus and a careful exposition of the difficulties and dangers of the operation of needling the kidney through the abdominal wall. Mr. H. J. Waring (London) describes the treatment of Gangrenous Hernia by resection and immediate union of the intestine, with an account of two cases. Dr. J. C. Webster, McGill University, Montreal, criticises recent views regarding Lateral Deviation and Rotation of the Uterus. Dr. Charles Steele records a case of Retinal Hyperæsthesia in which recovery followed seven weeks' confinement to an absolutely dark room. There are three other original articles.

Dublin Journal of Medical Science.—The opening article is one on the Use of Ergot in Obstetrics. The author, Dr. T. More Madden, is in favour of employing it freely, in full doses, under certain conditions which are carefully described.

Archives of the Roentgen Ray. London: The Rebman Publishing Co., Limited, 11, Adam-street, Strand. July, 1897. Price 4*s.*—This useful publication has now become a quarterly record of the proceedings of the recently formed Roentgen Society, and in its columns it is intended to publish original communications, notes, and correspondence bearing upon the new radiations, chiefly, of course, in their application to medical diagnosis. The present title adopted is obviously better chosen than the old one, which was "Archives of Skiagraphy." The first number thus issued under the auspices of the new society contains original papers on "The Nature of Roentgen's Rays," by Professor Silvanus P. Thompson; on "Roentgen Rays: a Survey, Present and Retrospective," by W. S. Hedley, M.D. Edin., the latter contribution being an excellent *résumé* of the

Digitized by Google

evolution and history of the x rays. These papers are followed by short descriptions of several cases, which are illustrated in some excellently reproduced skiagrams in a series of plates at the end of the number. The new journal is edited by Dr. W. S. Hedley, and Mr. Sidney Rowland, the editorial committee consisting of Dr. Mackenzie Davidson, Dr. John Macintyre, Mr. Thomas Moore, F.R.C.S. Eng., Dr. Morton, Mr. Campbell Swinton, Mr. Lynn Thomas, F.R.C.S. Eng., Dr. Norris Wolfenden, Professor Silvanus Thompson, and Dr. W. White.

Analytical Records
FROM
THE LANCET LABORATORY.

ÆSCULAP.

(THE ÆSCULAP BITTER WATER CO., LIMITED, 51, FARRINGDON-STREET, E.C.)

ÆSCULAP bitter water presents a composition analogous to most of its kind that are found in Budapest. It contains, according to our analysis, the sulphates of magnesium and sodium in nearly equal proportion. The analysis which we recently made is as follows, the results being expressed in grammes per litre: magnesium sulphate, 17·70; sodium sulphate, 16·77; calcium sulphate, 1·26; common salt, 2·50; and carbonate of soda, 0·56. Thus, whilst containing the purgative salts in approved proportion and relation to each other, it is also distinctly alkaline owing to the presence of carbonate of sodium, and in addition it contains a not unimportant quantity of ordinary salt. It is probable that it is the presence, though in small amount, of these latter ingredients which makes the administration of saline purgatives in a natural water more satisfactory than when the chemically pure sulphates are employed. The water acts mildly yet with good effect as an aperient.

BOVRIL STAMNOIDS.

(BOVRIL, LIMITED, 30, FARRINGDON-STREET, E.C.)

Bovril stamnoids are a very useful dietetic introduction Each stamnoid weighs a little over ten grains and, as the following analysis will show, presents the composition of a real nutrient. Our analysis was as follows: organic matters 78·70 per cent., moisture 6·20 per cent., and mineral matter 15·10 per cent. The total nitrogen amounted to 10·84 per cent., which is distributed over 35·60 parts beef powder, 31·10 parts meat extractives (creatin, &c.), and 12·00 parts albuminous matter and peptone. The stamnoid slowly disappears in the mouth and leaves no unpleasant after-flavour. Indeed the stamnoids possess an attractive beef-like taste. They should prove extremely serviceable as offering a palatable and reliable source of nutrient in an easily portable form. To athletes, cyclists, and travellers who have recourse to temporary nourishment, and to those who are in the habit of taking a light form of nourishment between meals, they should prove invaluable since they sustain as well as stimulate.

PURE CONCENTRATED COCOA.

(J. S. FRY AND SONS, BRISTOL.)

This cocoa is characterised by its extreme miscibility with hot water so that its valuable food constituents probably occur in a condition easy of assimilation and digestion. Analysis showed it to contain 30 per cent. of cocoa fat, which means that a reduction has been effected in the amount of the indigestible fat in the cocoa bean by about one half. The mineral matter amounted to 6·05 per cent. and its alkalinity, reckoned as potash, to 2 per cent. Since the normal alkalinity of the ash of cocoa with half its fat extracted amounts to 5 per cent. it is highly probable that a small proportion of a salt which on ignition exhibits an alkaline reaction has been added, the cocoa itself not giving the slightest evidence of free alkali. This accounts for the high degree of the so-called solubility which this cocoa exhibits. The peculiar method of manufacture adopted undoubtedly increases its dietetic value.

PURE COCOA ESSENCE (CAMEL BRAND).

(PEEK BROTHERS AND WINCH, LIMITED, 20, EASTCHEAP, E.C.)

This essence possesses an admirable flavour and develops an attractive aroma in the cup. It is thoroughly miscible with hot water, and contains practically no coarse ingredients. This is clear from the fact that on mixing the cocoa with hot water the liquid remains practically without sediment for some time. Analysis gave the following results: fat, 30 per cent.; mineral matter, 4·21 per cent., exhibiting an alkalinity equal to 1·04 per cent. potash. The cocoa contains no free alkali, but by its method of preparation the mineral matter obtained on incineration is increased and, *pari passu*, its degree of alkalinity. From these results the general excellence of this cocoa must be admitted.

QUAKER OATS.

(THE AMERICAN CEREAL COMPANY, CHICAGO.)

Rolled oats or whole oats flattened into wafers are, as is well illustrated in "Quaker Oats," a distinct improvement on the ordinary preparations, since while the rolling process secures a more complete extraction of the valuable food ingredients in the making of porridge, on account of the increased extracting surface exposed, the fat at the same time does not appear to undergo any objectionable change. It is well known that, owing to the fat becoming rancid, the flavour of ordinary oatmeal deteriorates. In "Quaker Oats" this flavour would appear to be preserved for an indefinite time. That the oats selected for the rolling process are of a superior quality is evident from the following analysis which we recently made: starch, &c., 65·77; albuminoids, 15·43; fat, 8·00; mineral matter, 1·35 per cent.; moisture, 9·45 per cent. Thus "Quaker Oats" contain a maximum proportion of each of the food constituents which places the oat above other cereals in regard to nourishing and sustaining value. A glance at the above analysis will serve to show at once that this preparation represents a complete food, and by its peculiar mode of preparation its nutritive qualities are made more available.

ANTI-DIABETIC WHISKY.

(JOHN DEWAR AND SONS, PERTH, AND 48, LIME-STREET, E.C.)

The ground upon which this spirit is claimed to be suitable for use by the diabetic patient will be easily understood from the following results of analysis: extractive matters, 0·035 per cent.; mineral matter, *nil*; acidity calculated as acetic acid, 0·0096 per cent.; alcohol, by weight 40·30 per cent., by volume 47·67 per cent., equal to proof spirit 83·54 per cent. The whisky, as might be expected, is pale in colour, but possesses the smooth and mellow flavour of a matured spirit. It is practically without extractives and acidity. The peculiar aroma and flavour of ordinary whisky is almost absent. In the present state of our knowledge in regard to diabetes, it is held essential that the patient should, if he drink whisky at all, only drink that which is of the purest kind and free from extractives and acidity. The spirit under analysis complies with these requirements, but its flavour necessarily suffers.

COMALTANA WINE.

(THE COMALTANA WINE CO., MARKET-STREET, HECKMONDWIKE, YORKS.)

The genuineness of this wine was abundantly established by the fact that it showed digestive action upon starch, which was more marked when the alcohol was removed by slow evaporation at a low temperature. Again, cocaine was easily isolated and identified. The wine is, in fact, a combination of

Digitized by Google

extract of malt and extract of coca leaf with port wine. Its alcoholic strength is somewhat below that of ordinary port, as will be seen from the following results, in which are included other items: alcohol, by weight 15·00, by volume 18·48, equal to proof spirit 32·38; extractives and sugar, 16·75 per cent.; mineral matter, 0·35 per cent. The wine possesses a strong malty flavour. It may be regarded as presenting the invigorating qualities of port wine added to the stimulating properties of the coca leaf and the nutritive as well as digestive qualities of an active malt extract.

EUCHININ.

(WIDENMANN, BROICHER, AND CO., 33, LIME-STREET, E.C.)

Euchinin is obtained by the action of chloro-carbonic ethyl-ether on quinine. With acids, in which it is freely soluble, it yields a solution exhibiting the fluorescent appearance of quinine in sulphuric acid. It is said to secure the therapeutic effects of quinine without introducing its unpleasant properties. Euchinin is stated not to disturb the appetite or to produce nausea. This new quinine combination is regarded as offering a satisfactory means of introducing quinine into the system when ordinary quinine leads to objectionable effects.

KRYOFINE.

(AGENCY: D. MISELL, 65 AND 66, BASINGHALL-STREET, E.C.)

To the already long list of new antipyretics must be added "Kryofine." Like phenacetin, it is a para-phenetidin derivative, and is, in fact, the condensation product derived from heating para-phenetidin with methoxyacetic acid. Phenacetin is aceto-para-phenetidin. "Kryofine" is said to effect a very decided reduction in temperature in febrile conditions, and is stated to be more certain than either antipyrin or phenacetin, and yet to have no unpleasant sequelæ.

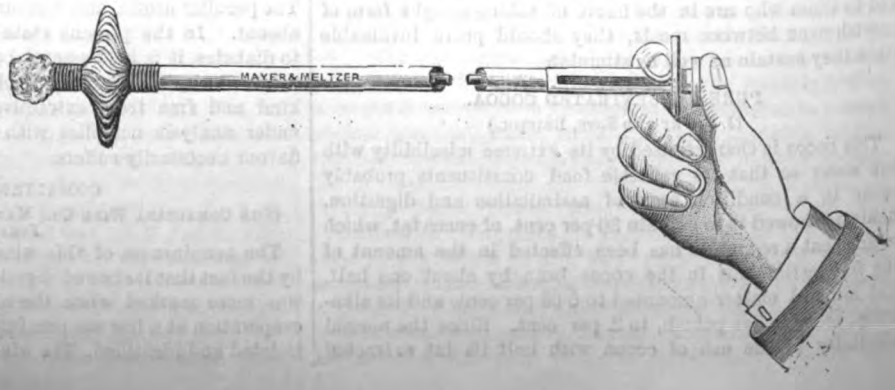
NEW PHARMACEUTICAL PREPARATIONS (WARNER AND CO., PHILADELPHIA).

(AGENTS: F. NEWBERY AND SONS, 1 AND 3, KING EDWARD-STREET, NEWGATE-STREET, E.C.)

Some excellent formulæ are comprised in the following preparations:—Cascara Elixir, from which the inert and griping principles have been removed; Elixir Salicylic Comp., a sweet-tasting preparation containing pure salicylates for administration in acute rheumatism; and Tono Sumbul, a bitter cordial with quinine-like taste, containing chiefly the extractives of sumbul root combined with calisaya, iron, and phosphoric acid. The latter preparation is said to be a useful stimulant and tonic to the nervous system, as in hysteria, delirium, and asthma, and is to be taken in tablespoonful doses before meals; Sumbul, or musk root, is also combined with asafœtida, sulphate of iron, and arsenic, in the convenient form of elegantly-coated pills, and to the pill list also may be added the chalybeate pill of the composition of Blaud's pill—that is, containing protosulphate of iron and carbonate of potassium in molecular proportion. We found that on dissolving a pill in water interaction speedily took place, pure protocarbonate of iron resulting. The chalybeate pill is also prepared containing extract of nux vomica ½ grain; this latter is an excellent combination as a ferruginous tonic. Another useful formula in the form of a pill is that which contains sulphite of soda 1 grain, salicylic acid 1 grain, and nux vomica ¼ grain, which has been prescribed with good results in hyperacidity and disturbed digestive function. Lastly should be mentioned the granular effervescent preparation of hydrobromate of caffeine, which has been found valuable in the relief of nervous or sick headache. All these preparations are admirable specimens of the advances in pharmaceutical preparations.

New Inventions.

NEW HERNIA CORSET.



THE use of the truss or belt commonly employed at present in cases of umbilical hernia is attended with inconveniences which it is the object of this appliance to avoid. The instrument which I have designed for the purpose has the further advantage that it acts also as an abdominal bandage or support. It may be easily and readily applied and worn without discomfort. It is employed in combination with a corset, and consists of a spring, preferably constructed of a band or strip of sheet steel, and curved. The centre of the spring is attached to the lower end of one of the corset busks or to the lower end of an auxiliary busk or support such as is sometimes worn with corsets, with the concavity of the curvature outside. To the outer ends of the spring there are attached studs, buckles, buttons, or the like, to which straps may be secured. The straps which are used each have one end attached to the corset at a point about midway between the front and the back, or nearer to the front or back, and near the lower edge. At about the point of attachment of the spring to the busk a pad is secured so as to come upon the umbilical region when in use. This pad may resemble the pads used with umbilical trusses and will vary in construction to suit the particular hernia for which it is intended. In use, after the corset is in place, with the pad over the hernia, the straps from each side of the corset are connected with the ends of the springs and are adjusted until the proper degree of pressure is produced by the consequent flattening of the curvature of the spring. In removing the corset it will be necessary to detach only one of the straps from the spring. Gussets of elastic web may be inserted in the lower edge of the corset, and the straps, or a portion of them, may be made of elastic web or of coiled springs or the like. It can be obtained from Messrs. Arnold and Sons, London.

Blackpool. F. W. A. STOTT, M.A., M.B. Oxon.

AN IMPROVED ŒSOPHAGEAL PROBANG.

THE following modification of the umbrella probang has been devised with the object of obviating the well-known difficulties experienced in the use of the ordinary pattern—viz., the premature opening during insertion, and of opening and withdrawing, which necessitates the use of both hands. The probang is constructed in the usual way so far as the

Digitized by Google

bristles, catheter, &c., are concerned, but the end which is held by the operator is so arranged that the whalebone does not protrude, but terminates about an inch from the end of the catheter, and is fixed to a disc by a pin which passes through lateral slits in the catheter. When inserting the probang it is held by the end beyond the disc and so prevented from opening; it is then opened and withdrawn by pressing on the end with the thumb, as shown in the illustration. By this means one hand is free to steady the patient's head or to hold a tongue spatula or gag. Messrs. Mayer and Meltzer, of Great Portland-street, are the makers.

King's College Hospital, London. C. J. MAYHAW.

THE BATTLE OF THE CLUBS.

THE ACTION OF THE PROFESSION AT GREAT YARMOUTH.

AT a recent meeting of the Great Yarmouth District Committee of the Incorporated Medical Practitioners' Association it was decided to send a memorial to every licensing body in the United Kingdom calling attention to the evils and abuses at present existing in connexion with the administration of many clubs and medical aid societies, and if possible to procure an expression of opinion from the licensing bodies, on the conduct of those of their graduates or diplomates who, by holding appointments under such clubs or societies, aid, abet, and perpetuate the abuses and evils which exist in connexion therewith.

We publish this memorial below, thus bringing the matter prominently before the profession and to the cognisance of other local societies of medical practitioners, which may thus be led to coöperation and possibly to adoption of similar measures calculated to bring forcibly to the notice of the licensing and governing bodies the abuses now obtaining in connexion with medical aid societies, clubs, and hospitals.

TO THE { SENATE / COUNCIL } OF THE.....

We, the undersigned—being, with one exception, all the registered medical men engaged in private practice in Great Yarmouth—beg leave to bring the following facts under the notice of your { Senate / Council } as the governing body of one of the corporations entitled under the Medical Acts to grant { degrees / diplomas } qualifying their holders to practise medicine, surgery, and midwifery in the United Kingdom:—

1. In Great Yarmouth, as in other districts of the United Kingdom, certain grave abuses have grown up of late years in connexion with the systems of "Medical Aid" for the working classes organised by the friendly societies and by certain industrial life assurance companies, and other lay associations.

The principal abuses referred to are:—

(*a*) The admission of persons not needing such assistance to medical benefits intended primarily for the relief of the poorer classes.

(*b*) The admission of women and children to these benefits at entirely inadequate rates of payment for the medical officer.

(*c*) Specially in the case of industrial assurance and similar societies a system of indiscriminate canvassing whereby the private patients of other medical men are solicited—directly for the company, indirectly for its medical officer.

(*d*) The conduct of medical practice by lay organisations purely as a commercial speculation, this being most flagrant where, as in some cases, the medical officer receives a fixed salary; and beyond this amount the fees accruing from his work are appropriated as the profits of his non-medical employers.

2. For the purpose of checking these and similar abuses all but one of the medical practitioners residing in Great Yarmouth combined, and as one result of their association a joint request was made to the friendly societies for a conference with a view to an amicable adjustment of the matters in question, but with few exceptions the friendly societies absolutely refused this request, dismissed their medical officers, and proceeded to form a medical institute in the constitution of which all the above abuses are maintained and even increased.

3. The posts of medical officers to this institute were advertised in the lay press, and as a result, notwithstanding the condemnation of such methods of practice by the medical journals and by the general voice of the profession, and in spite also of the fact that those accepting these appointments must knowingly, wilfully, and openly assume the position of assisting a certain section of the public to defeat the local medical men in a matter involving the vital interests of the profession, qualified medical men were, we regret to say, found willing to take these posts.

4. One of our members had previously acted as the medical officer of an industrial assurance company offering "medical aid" as an attraction to its insurers, paying its medical officer a fixed salary, and canvassing for patients from door to door. This office he has resigned, but in the absence of any declaration as to these appointments by the General Medical Council, or by the universities and colleges granting medical qualifications, the company has, we believe, easily found a substitute.

5. Such facts as we have recited can be quite paralleled in the experience of other towns and districts of the United Kingdom, and appear to us to call for the careful attention of the various governing bodies entrusted with the granting of medical qualifications and with the control of those qualified.

The dignity and independence which are essential to the adequate discharge by medical men of their duties to the public are gravely imperilled by these abuses. In particular (*a*) canvassing by lay bodies on behalf of medical men employed by them is plainly contrary to the first principles underlying proper professional relations, and appointments depending on such canvassing ought not to be permitted to be held by registered medical practitioners; (*b*) it is impossible for a medical man, acting under the control and direction, and entirely subservient to the pecuniary interests of a purely trading company which traffics in medical attendance, to satisfactorily perform the duties of a medical practitioner; whilst (*c*) the unchecked extension of the club system to all classes of society threatens a general conversion of medical practice from the basis of private relation to that of public contract, a conversion which we think the medical profession should resist with all its strength not more in its own interest than in that of the public.

We therefore beg leave to submit the following questions to the consideration of your { Senate / Council }:—

(*a*) Is the holding of appointments such as are herein described compatible with the conditions under which your { degree / diploma } is granted and held?

(*b*) If the holding of such appointments by your { graduates / diplomates } does not contravene the existing regulations, does not your { Senate / Council } consider that, in the interests of the medical profession and of the public, by-laws forbidding such practice should be adopted?

(*c*) Is not your { Senate / Council } of opinion that for a medical man to hold such appointments should be declared by the General Medical Council to be conduct infamous in a professional respect, and if so, will your { Senate / Council } instruct its representative on the General Medical Council to support such a declaration?

(Signed)

COVENTRY PROVIDENT DISPENSARY AND ITS MEDICAL STAFF.

The medical staff of this old—perhaps the oldest—provident dispensary have addressed a memorial to the committee asking for several alterations in the rules. One was for the fixing of a wage limit; another was to have a rule cancelled which requires the appointment of a new medical officer when the aggregate salaries of the staff equal an average of £350 each; another to allow all the members of the staff to sit on the committee instead of only two; and a fourth to raise the subscription for children where a concession for large families is now allowed. These are all most reasonable propositions; certainly the first and the last two. Yet the committee have declined to agree to them, except to a slight rise in children's subscriptions. The memorial has been twice presented, and the requests have been twice refused. The staff owe it to themselves and the profession to be firm in demanding compliance with such just claims. In doing so they should have the support of the profession of the town and neighbourhood. Without this they could scarcely be expected to be firm. According to the *Birmingham Mail* the committee are not in a conciliatory frame of mind, and are prepared to engage a medical staff exclusively for the dispensary, as is being done at Yarmouth and other towns. Such high-handed disregard of the just claims of the profession would not be possible if the profession were true to itself. Of this the staff must judge for themselves. They are not called on to play into the hands of those who are ever ready to accept offices vacated by others and to reap what they have not sown.

FOREIGN UNIVERSITY INTELLIGENCE.—*Lemberg:* Dr. H. Schramm has been recognised as *privat-docent* of Surgery.—*Prague* (*Bohemian University*): Dr. V. Slavik has been recognised as *privat-docent* of Forensic Medicine.—*Utrecht:* Dr. Zwaardenmarker has been appointed to the chair of Physiology in succession to Professor William Engelmann, who goes to Berlin.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 18, 1897.

THE duty imposed on the profession by the resignation of Dr. RENTOUL is one of the gravest kind. The functions of the General Medical Council are far-reaching and likely to become more so. It has the power to very largely determine the course and character of medical education and even to affect the nature of the preliminary education of the country. It has the power, with an almost absolute discretion, of defining infamous behaviour in a professional respect, and of removing any registered practitioner who has been guilty of it from the Medical Register. It is asked from time to time to favour the Privy Council or the Government with its opinions on questions of legislation affecting the profession or the health of the public. These are the great functions of the General Medical Council, and Parliament in its wisdom has determined that the registered practitioners of the country shall elect a sixth part of the General Medical Council. Some highly conservative members of the profession think that this recognition of the claims of the registered practitioners to a voice in the General Medical Council is all a mistake—a sort of interference with the divine right of the universities and the medical corporations to rule the profession and to be the sole exponents of what is needed for the education and discipline of medical men. Others think that Parliament was right in making provision, in 1886, for having the judgment of the practitioners of the country as such on the work of the General Medical Council, and that the principle of direct representation needs a little more extension. They are of opinion that the duties of the General Medical Council would be discharged a little more expeditiously and effectively by a larger importation of men familiar with the details of medical practice and the defects of medical education. This last opinion is held by a large number of practitioners, probably the majority of those on the Medical Register. But it must be admitted that the evidence is not decisive on this point. The doubt arises from the fact that the profession has never put forth its strength, or even three-fourths of its strength, on the occasion of the election of direct representatives, and that at the last election there was a great defection of voters and a great discord of opinion among those who did vote. Out of 22,577 voting papers sent out only 11,990 were returned validly signed and filled up. It will be difficult to convince statesmen that the profession cares about direct representation if nearly half the voters on the Medical Register abstain from voting.

There is a duty on the profession as urgent as voting, and prior in point of time to voting—that is, the duty of selecting candidates. The misfortune of the past elections, and especially of the last one, was that the interest of the profession was so divided over a number of candidates that no individual candidate could boast that he had been returned by even a third of the profession. There were ten candidates for three vacancies. The first on the poll had 6646 votes; the last had 143. The profession cannot expect its direct representatives to do much on such terms as these. Neither the General Medical Council nor the public can take direct representation seriously if the profession is to drift in the matter of selection and at the end to be hopelessly divided among ten candidates. The first and most urgent duty then of the profession is the selection of a candidate. Is it beyond hope that the profession and its associations should for this purpose of selection of a fit and proper candidate to represent over 22,000 registered medical men comport itself as if it were one man. That is the only way to make direct representation respected. There is no lack of men either in the Provinces or in London whose experience and character and standing in the profession would add to the weight and efficiency of the Council. If one such were selected by a representative group of men in the profession he would come forward with such advantages and recommendation that his election would be certain, and his influence thereafter in the Council would be considerable.

The occasion is really a serious one. We have said nothing about the untimely vacancy, which for the future will put the profession and the Council to the expense of a double election. The gentleman to be elected will be elected for five years, and his term of office will expire a year after that of his two English colleagues; and such an anomalous and inconvenient state of matters will last till an absurd defect in the law is remedied. Dr. RENTOUL has, no doubt, reasons which are satisfactory to his mind for the perplexing step he has taken before he has been a year in the Council and just when he would have had his opportunity of expounding to the Council the views which he has pressed so incessantly on the profession. We may hope that these reasons will satisfy the electors who returned him in December last. We have no wish to spend our time or space in devising excuses or explanation of an act which none can explain but Dr. RENTOUL himself. Be this as it may, the vacancy is a fact, and has to be promptly filled up; and what we impress on our readers is that the whole circumstances of direct representation are such now as to make this election one of peculiar importance. The members of the profession who care least for direct representation cannot wish to see it brought into discredit by want of interest or want of method in those who constitute the great bulk of the profession. Neither the dignity of the profession nor the interest of candidates can be served by a general apathy—by nobody doing what is supposed to be everybody's business. The institutions of the profession recognised by law are of no use for this purpose. They are over-represented already. The only organisations that can intervene here are its voluntary associations. The strength of them will be judged by their action at this moment. If all that has been said lately in high quarters about the powerlessness of one great organisation is not to receive a striking confirmation that body will have to show more power of initiative, and courage of selection and of preference than it showed last year. We have only two words to say in conclusion. One is that the vacancy arises by the resignation of a member living in the provinces, and

Digitized by Google

that it is natural that the provinces should think themselves entitled to the seat if they can agree upon one suitable candidate. The other is that no time is to be lost. We give in another column the legal steps of the procedure of election for the guidance of candidates and their friends, from which it will be seen that in less than a month the election will be over.

WHY should medical practitioners be appealed to only in cases of pronounced disease? Why should they not be asked for a professional opinion even by those who to outward appearance are in good health? Just as the wise administrator or manager overhauls his books from time to time to make sure that no item has crept in or been omitted which may eventually disturb the balance, so the "intelligent custodian of his own health" will have his condition professionally examined at intervals more or less frequent so as to satisfy himself that the complex machine he calls his "system" is in good working order. This is one of many practical corollaries to be gathered from Dr. ANGELO MOSSO'S latest book—the work of a biologist, a physician, an athlete, and, we may add, a poet—which, dealing with one great and increasing province of human activity, appears opportunely to allay misapprehensions and to give sound advice or even warning for the benefit of all whom that province attracts. "La fisiologia dell' Uomo sulle Alpi" (the Physiology of Man on the Alps) is its title, and it should be read after a judicious perusal of the writer's attractive treatises on "Fear," "Fatigue," and "Brain Temperatures," supplementing these, as it does, in many important directions and concentrating the *ensemble* of their findings and conclusions on corporeal exertion in general and mountaineering in particular. Himself a "peak-stormer" with a distinguished record, Professor MOSSO approaches the subject with an authority which only the life-long worker in physiology and experimental hygiene can command, and he uses his knowledge so genially, and illustrates it from such a fund of experience as to inspire sympathy and gain a hearing in quarters impervious to mere didactic exposition, however well accredited. For the observations on which the present book is based he had at his service ten soldiers of the Alpine regiment under the command of an army surgeon; he had also a working laboratory fitted up in a cabin 4500 mètres above sea level; he could subdivide the ascent (of the Monte Rosa) into diverse stages with encampments and other shelters, so as to overtake these said stages at different rates of rapidity, with the soldiers divided into two companies; he had, in short, an array of "means to ends" never before enjoyed by investigators in the same province; and if special circumstances obliged him to limit his sojourn on the peak of Monte Rosa to ten days, he could with advantage recall the words of his able precursor, Signor G. ZUMSTEIN, who, reporting to the Turinese "Accademia delle Scienze" the results of his first ascent of the same mountain, observed: "Il faut s'estimer heureux si l'on peut faire la moitié des observations aux quelles on s'est préparé." From a book which has few pages not pregnant with acute remark or practical comment it is difficult to make representative excerpts, those selected seeming a moment afterwards to be surpassed by others in freshness and value. But omitting Professor MOSSO'S corrections of previous investigators from SAUSSURE downwards as to "respiration on the mountains," as to the phenomena of the circulation, as to the "Mal di Montagna," and such like, we may cal attention to the paragraphs on "Automatism" and its effects on the mountaineer, always marked, and not seldom disastrous. "Let the Alpine climber never forget," he says, "that he may become an automaton through fatigue when it is no longer the brain that gives him the impulse to walk, but a blind, unconscious force." In these circumstances he becomes dead to danger, because all his sense-perceptions and his mental alertness are blunted. What seems daring in this condition is simply the indifference of insensibility. It is not "the offspring of courage; it is the expression of a pathological fact due to the nervous exhaustion which annuls the consciousness of peril." Temporary impairment of memory is, he points out, a constant effect of fatigue incurred in mountain ascents; it is part of the general diminution of sensibility caused under the same conditions. The muscular sense similarly undergoes a change for the worse. "Look," he says, "at the gait of those who are approaching the end of a long march; their semi-collapsed attitude, their listlessness, depend in great part on this—they feel the ground less well beneath them." This is a dangerous condition to fall into in an Alpine ascent, an error in footing not being corrected with that promptitude on which safety so often depends. The acuteness of the eyesight frequently diminishes—even the sensation of light. This phenomenon Professor MOSSO illustrates from his own experience, and then he proceeds to consider the effects of exhaustion on so-called "nervous persons"—a difficult subject, because, as he says, we do not know how much real energy they have at command, while they often start on an ascent without estimating "quid valeant humeri, quid ferre recusent." Again, they have no idea of what outlay of force the exertion may cost them. "It is not to be wondered at," he remarks, "that grave incidents overtake them even on short expeditions." They fall into what he terms "un errore fatale di contabilita fisiologica." As a first effect, fatigue produces an excitement which engenders the mistaken belief that they are really stronger. This he illustrates by a series of effective examples drawn from experience. "The excitement produced in the system," he continues, "by the 'scorie delia fatica' (the débris of metabolism) prevents their realising how much potential force they still retain. ..... Those individuals who most nearly approach systematic bankruptcy are unfortunately the very individuals who most enjoy the nervous excitation produced by fatigue. They court it with the craving of the morphinomaniac, who avails himself of morphine not to sleep, but to excite himself. Everyone referring to his acquaintanceships must recall some slightly-built, especially nervous and hysterical subjects, who boast they have never known what fatigue was. ..... Physician and patient alike are often drawn into error by this physiological paradox; the patient is recommended to court movement as a means of working off exuberant force, while the ratio of physical exercise is already excessive and ought instead to enjoin repose. FÉRÉ has just shown that nervous fatigue and profound emotion render us more

Digitized by Google

vulnerable to poisons. The fatigue of the muscles is indeed a poison. Strange and much to be dreaded is this condition of the weakly. Their body resembles a 'going concern' or a commercial house in which the cashier (the nervous system, in that case) does not let the principal know either what sums he has in the till or what outlays the house is continually incurring. Matters go on without the possibility of ever striking a balance. Light-heartedness and waste increase fatally the nearer the approach to bankruptcy.' How true this is in everyday life, how disastrously true in the world of bicyclists, amateur athletes, and, above all, Alpine climbers, is known to none better than to the medical practitioner.

AT the third general meeting of the Twelfth International Medical Congress recently held at Moscow Professor LEYDEN, of Berlin, read a paper on a subject which has many times been brought before the notice of medical men, not only during the last few years, but upwards of 200 years ago—namely, the contemporary methods of treating tuberculous patients, and the need of Government control over them. The terms "200 years ago" and "contemporary" may seem contradictions, but at the former period in Italy medical men came to the conclusion that "consumption" was contagious, and most stringent measures were adopted to attempt to control it by notification, isolation, and disinfection, but apparently without effect. Within the last decade renewed efforts have been made in the same direction. CORNET'S[1] experiments have done much to accentuate the need for the proper disposal of the sputa of phthisical patients, and the authorities of the Brompton Hospital for Diseases of the Chest have adopted measures in this direction. It has several times been suggested that pulmonary tuberculosis should be made a notifiable disease—that is to say, in the words of Professor LEYDEN'S paper, that there is "need of Government control over them" (the patients). Although at first sight this would seem to be the correct way to deal with an infectious disease, there are numerous difficulties to be overcome. In the first place such a proposal presumes that the contact of tuberculous patients with healthy individuals is a source of danger to the latter. That this is not so in the same way as in the case of other infectious maladies is evident from everyday experience. Another difficulty is that in the majority of instances the disease has existed for some considerable time before it has been recognised, and the clinical and post-mortem records of our general hospitals would seem to indicate that many patients have suffered from pulmonary tuberculosis without ever having been aware of it, so that a satisfactory notification would be impossible; but on the other hand it behoves every practitioner who is attending a patient suffering from pulmonary tuberculosis to give careful directions as to the disposal of the sputa and the disinfection of linen (especially handkerchiefs) likely to be soiled with the expectoration.

[1] Zeitschrift für Hygiene, 1889, v. vi.

The principal points in treatment were fully referred to by Professor LEYDEN. Like most other physicians who have had a large experience in treating the disease now under consideration, he is reluctantly compelled to admit that up to the present time we have discovered no means of actually attacking the bacillus itself when it has succeeded in invading the lung, and we have therefore to strengthen and reinforce the powers of the individual so as to enable him to withstand the influence of the microbe. He pointed out that the principal points in this mode of treatment are:—(1) Choice of a suitable climate; (2) a good air, free from dust; (3) good nourishment; (4) exercise; (5) methodical treatment of the patient in special institutions; and (6) medicinal treatment as auxiliary to the general treatment. Cold fresh air was of the greatest importance; and a suitable amount of exercise should also be permitted. All the various points, Professor LEYDEN maintained, in a successful scheme of treatment were only attainable in a properly conducted sanatorium. With this statement we can only partially agree. It is, no doubt, to a great extent true, but not as regards all classes of patients, and for this reason, patients must be divided in accordance with their financial means. Patients who cannot afford climatic treatment—that is to say, those who cannot afford to live in a climate suitable to the condition of their lungs—would of course do better to avail themselves of such institutions, but others, we believe, would do wisely to provide themselves with a suitable home, temporary or permanent, under medical direction, apart from the constant society of patients afflicted similarly to themselves. Our large chest hospitals are to a great extent such institutions as Professor LEYDEN suggests, with the exception of climate, which could certainly be improved upon; and the Brompton Hospital is at the present time making an endeavour to establish a branch in the country, where more salubrious climatic conditions prevail. But at the same time the statistics of our chest hospitals are satisfactory as showing what the other conditions—good food, cleanliness, and rest—can do.

Climate is of course one of the most important points in connexion with tuberculous disease; but it is not everything, and it is possible to be too hasty in advising patients to "go abroad." Other things must be considered apart from the stage of the disease and other medical points; the domestic and monetary circumstances may actually render it impossible for the patient to leave England. It is in such cases that the formation of such institutions as Professor LEYDEN suggests would prove of the greatest service. Our south coast offers a fairly favourable climate for cases of pulmonary tuberculosis. What is known as the "open air treatment" has proved very successful, and this has already been adopted at Bournemouth, if not at other places. The Royal National Hospital at Ventnor is an excellent institution, but the number of beds is limited and the authorities quite rightly are most strict in the selection of cases, and there are consequently large numbers of patients in the more advanced stages of the disease seeking admission to whom increased accommodation would be the greatest boon, as they are otherwise entirely unable to take advantage of the climate which our south coast offers.

Annotations.

"Ne quid nimis."

THE CHURCH AND SANITATION.

WE have received a reprint of the annual sermon of the Church Sanitary Association, delivered in All Saint's Church, Tufnell Park, by the vicar, the Rev. W. J. Hocking, on Aug. 1st. It is an eminently practical discourse and full of plain speaking, as witness the following: "Science is making it clearer and clearer every day that not only diseases, but a very large proportion of the deaths of the country are attributable to causes which have been evolved out of things for which men are directly or indirectly responsible. It is, therefore, not only foolish piffle, but insulting ignorance, to say that the good God wills these things, and that we must resign ourselves to them." There is a mediæval simplicity and homeliness about these remarks which go far to excuse the lapse into slang terms. We are in full accord with Mr. Hocking when he contends that dirt and disease are not part of the divine order of things, and also that it is the duty of the Church to care for the bodies of men as well as their souls. Formerly she always did; the first hospital in London was a monastic establishment; it was the Church that drained fens, brought waste lands into cultivation, and taught people the advantages of living a healthy, regular life by rule. Even as late as the seventeenth century it was the Orthodox church of the East which provided for the care and isolation of lepers, and every parish priest going in and out among his flock ought to impress upon its members the paramount necessity of cleanliness, and, as Mr. Hocking says, not be afraid to tell landlords when their property is in an insanitary condition. The simple laws of health and sanitation ought to form a part of the examination of every candidate for ordination. Doubtless many will say it is not the business of the clergy to concern themselves with such matters, but we contend that it is, for amid unhealthy and filthy surroundings a healthy and moral mind is all but impossible.

ANTI-TUBERCLE SERUM.

AT a meeting of the American Medical Association held at Philadelphia last June Dr. Paul Paquin, of St. Louis, Mobile, gave an account of a considerable number of cases which had been treated with anti-tubercle serum, the results being in his opinion extremely favourable. The substance of Dr. Paquin's paper has been published in the *Journal of the American Medical Association* of July 17th last. It seems that a tubercle antitoxin has been prepared in St. Louis under his direction ever since the year 1894, and in January, 1895, he presented to the St. Louis Medical Society a report of the results obtained in 22 St. Louis City Hospital patients who had been treated exclusively with serum for three months. Most of these patients were eventually lost sight of, but it is known that three of them are still alive, following their occupation and apparently well in health. A second report of entirely new cases was made to the St. Louis Medical Society in March, 1896, and included the recovery of 16 cases of pulmonary tuberculosis, 2 of which were acute and 14 chronic. In this report Dr. Paquin stated that "of 100 cases treated in a period of eighteen months the following results obtained: In the first and second stage, as understood in general practice, 14 recovered; in the second stage, improved or checked or still improving at the time, 26; among these 26, 12 seemed to have really recovered, although the time had not been long enough to warrant positive assurance; there had disappeared from observation in all stages, 35; died during treatment, begun at the third and fourth stages, including 10 moribunds who insisted on trying the treatment, 25." In September, 1896, he presented a report to the Virginia State Medical Society of a total of 226 cases of tuberculosis exhibiting the following symptoms: Destructive broncho-pneumonia with cavities, 37; destructive broncho-pneumonia without recognisable cavities, 66; diffuse febrile pneumonia, with or without a destructive process, 19; diffuse non-febrile broncho-pneumonia, with or without destructive cavities, 19; circumscribed febrile broncho-pneumonia, 35; circumscribed apyretic broncho-pneumonia, 13; not described with sufficient accuracy for classification, 32; and extra-pulmonary tuberculosis, 5. The results of serum treatment were as follows: Recoveries that seemed complete and permanent, 40; apparent recoveries, with cavities *in statu quo*, 3; improved, capable of performing usual duties, 41; improved to a lesser degree, 69; number of deaths reported, 32; and disappeared from observation or under various treatments, 41. It was further stated that the patients' weight was increased in 125 cases, unchanged in 15, decreased in 27, not recorded in 59. At the meeting last June Dr. Paquin presented a report of 67 cases treated last year and not included in the foregoing statistics. The results of treatment were as follows: Recoveries that seem complete at present, 17; improvements to a considerable degree, 35; improvements to a lesser degree, 11; deaths, 4. This report does not include the numerous cases in which serum was tried for moribund patients, or in more favourable cases for too short a time, neither does it include a number of cases improved in the last few months by using serum by rectal injection.

THE VESTRY AND THE REPORT OF THE MEDICAL OFFICER.

THE following resolution was recently passed by the Vestry of St. George the Martyr, Southwark, with reference to Dr. Waldo's report:—

"That in the opinion of this Committee [Public Health and Sewers] the appendix to the medical officer of health's report contains a large quantity of unnecessary matter, and that the vestry clerk communicate with the Local Government Board, directing that reports, papers, and regulations which have not previously been submitted to the authority or issued for the first time during the year be excluded from future reports."

The Local Government Board was accordingly communicated with, and their reply was read at the meeting of the vest y held on Sept. 8th. It ran as follows:—

"Local Government Board, Whitehall, S.W.
"4th August, 1897.

"SIR,—I am directed by the Local Government Board to advert to your letter of the 13th ultimo enclosing a copy of a resolution passed by the Vestry of the Parish of St. George the Martyr, Southwark, expressing their opinion that the appendix to the Annual Report for 1896 of the Medical Officer of Health for the Parish contains a large quantity of unnecessary matter. I am to state that it rests with the Vestry to decide what documents shall be reprinted as an appendix to the annual report of the medical officer of health, but I am to observe that in the present case there are matters contained in the appendix which, in the opinion of the Board, are of more importance in connexion with the report, and some of which might properly have been included in the report itself.

"I am, Sir, your obedient servant,
(Signed) "H. C. MOWAN, Assistant Secretary.
"J. A. Johnson, Esq., Clerk to the Vestry of the
"Parish of St. George the Martyr, Southwark."

It will be seen that "honours were easy" in this important dispute as far as the result of the appeal to the Local Government Board goes. On the one hand, the vestry is told that it rests with them to decide what documents shall be reprinted as an appendix to the annual report of the medical officer of health, which, we presume, is not exactly Dr. Waldo's contention; but, on the other hand, the Board points out that the vestry have not the necessary knowledge to exercise the discretion which they appear to possess, as the matter which it was desired to exclude appears to the Board to be of particular importance to the report. Our own opinion on this matter has been already very definitely stated. The

Digitized by Google

action of the vestry of St. George, Southwark, has been misguided and, though possibly honest in intention and devoid of private ill-feeling, has given the public a right to withhold confidence from them.

"STONES IN THE HEAD."

THERE are some curious pictures in the Dutch museums which would suggest that at one time the removal of "stones in the head" was a common operation. Thus in the picture of Pierre Brueghel le Vieux in the engraving room of the Amsterdam Museum, and of Van Bosch in the same collection, and also in the picture by Jan Steen, in Boijmans Museum, Rotterdam, all of which are of the sixteenth century, there are unmistakable indications of a patient undergoing an operation for the removal, not of one stone, but of quite a pile of stones. In an interesting paper by Dr. A. Cartaz in *La Nature*,[1] he applies himself to the question as to what was the operation which the painter intended to ridicule. It is probable that the pictures related to operations which were for the most part purely factitious and addressed to subjects of disordered minds. In other words, it was an opportunity which quacks even at that time did not fail to seize. In the picture by Brueghel le Vieux may be seen, hidden under a stool, a confederate with a basket full of stones, ready to be passed at the proper moment, as the ball is passed to the juggler. In Jan Steen's picture the operation is evidently being conducted at home, but here the operator is not without skilful accomplices—the matron, his habitual assistant, with her cunning expression, and the urchin who laughs at the humbug of the thing, as he passes the pebbles which the crafty charlatan causes to roll over the neck of the suffering patient.

SANITARY REFORM IN ALGERIA.

ACCORDING to the French journal *Le Radical* medical and sanitary reform has at length begun to make some progress amongst the native population of Algeria. A few years ago attention was directed to the subject by Dr. G. Martin, a French medical man, who published letters wherein he bewailed the supposed fact that English females had long pervaded the whole of Kabylia under the guise of tourists, whereas in reality they were zealous propagandists who could not be said to inculcate love of France during their ministration. It behoved the French Government to exercise a strict surveillance over these so-called missionaries, but at the same time some encouragement ought to be afforded to national enterprise so that the duty now usurped by foreigners might be carried out under the control of self-sacrificing patriots. This wearer of tinted spectacles then went on to announce the welcome news that at last a step in the right direction had been taken, Madame Chellier, a distinguished graduate of the Paris Faculty, having organised an expedition under the auspices of the governor of the province, M. Cambon. At that very moment this lady was actively engaged in disseminating the truths of medicine and hygiene amidst the benighted female inhabitants of the mountainous district of Aurès, and a commencement having been made with so much energy and success it was confidently to be expected that the movement would speedily attain to the dimensions it so richly merited. Madame Chellier has now sent in two reports, for 1895 and 1896 respectively, but although she has accomplished much *Le Radical* is still discontented. "How far, alas! we still are from what the English are doing in India," exclaims the writer in a burst of candour, "the Governor of Algeria ought not only to persevere in the course he has adopted, but also to do more—very much more!" It was in the beginning of 1895 that Madame Chellier, quitting Batna, first penetrated the Aurès highlands, travelling on horseback by well-nigh impracticable paths, sleeping for the most part in a little tent, and affording medical aid to nearly seven hundred patients in the villages and hovels of this rude region during a period of five weeks. "When we read the account of the barbarous practices resorted to by the matrons attending on the women who are about to become mothers"—continues *Le Radical*—"we cannot but be seized with sadness and pity at the thought that innumerable victims must inevitably succumb owing to the ignorance of these creatures, and that in a country which has been French for half a century." In 1896 it was not five weeks but five months which the courageous Madame Chellier passed in the Aurès, and also in part of Kabylia. In the course of this journey she vaccinated 1400 Arabs of both sexes in places that were periodically decimated by small-pox. She likewise treated 1200 sick people, and all the time she lost no opportunity of teaching the matrons how to perform their duty properly. The work accomplished by Madame Chellier has been unquestionably most valuable, but no one is better aware than she is of its insufficiency. In her opinion the Algerians are ripe for sanitary reform, and all that is required is direction and instruction. The first thing to be done is to establish accouchement schools for female pupils, of whom it will be easy to obtain a sufficient supply. "If the Governor-General of Algeria will only take to heart the work done by the English in India he will render the greatest possible service to France," but in order to arrive at this result access to the native interiors is essential, and female practitioners alone can make their way to where the women live.

[1] A translation of this paper appears in the August number of Appleton's Popular Science Monthly.

A NEW FIRE EXTINGUISHER.

ACCORDING to a statement published in the July number of the New York *Insurance Times* the hose and hydrant have found a formidable rival in their work of fire extinction. The new comer is a powder which is said to be so light as to be easily carried by a draught of air in any direction. It does not injure furniture or other objects with which it may come in contact, it cannot freeze, nor does it lose in efficiency by age or climate. It requires no machinery for its application. Its powers were recently demonstrated by a test experiment carried out under the direction of the New York Fire Department. A wooden building furnished with a flue thirty-eight feet long was set on fire, and when well alight was treated with the new extinguisher. Two tubes were used, and in seventeen seconds the fire was subdued, the entire inner surface of the flue having been charred in the meantime. We are not informed as to the composition of this powder. If it be as safe as it appears to be efficacious, it should prove a useful addition to the safeguards against fire already employed in the household. Its lightness ought certainly to enhance its value in dealing with that occasionally dangerous bugbear—fire in the chimney.

"DEATH BY LIGHTNING."

WITH reference to an annotation bearing the above heading in THE LANCET of Sept. 4th we have received a letter from a medical correspondent pointing out that there were certain inaccuracies in our account of the details of the sad case, and kindly supplying us with the following interesting particulars which, we think, should not go unrecorded. Our correspondent saw the deceased about four hours after death, by which time the body had been undressed and washed. The hair was singed in front of and above the right ear, and there was a little blood in the meatus. The skin of the front of the neck was dark-red and stiffened, so that it did not pinch up so easily or in so thin a fold as the healthy skin. This change extended to about

Digitized by Google

the posterior edge of the sterno-mastoids, and faded gradually. Down the chest and abdomen were two well-defined, sharp-edged, irregular, ribbon-shaped bands in which the skin was dark-red, uniformly depressed, and hard. Quite at the lower part of the abdomen these ceased, and here again there was singeing of the hair. The thighs were quite untouched, except for a few (six or eight) small oval spots of this reddened, depressed skin scattered over the upper part of the right thigh (front). On the front of the left leg, from knee to ankle, were several irregular streaks of the same nature as the bands on the chest, some of them from two to three inches long and about a quarter of an inch broad, and there was a similar condition on the back of the right leg, from knee to ankle. On the under surface of the right heel was a transverse laceration an inch long with healthy edges. Nothing corresponding existed on the left side. No bones were broken, no skin was torn off, nor was the right leg torn or blackened.

HABITUAL DISLOCATION OF THE SHOULDER.

HABITUAL dislocation of the shoulder, though rare, has occurred often enough to have attracted some attention. An important article on the subject by Dr. H. L. Burrell and Dr. R. W. Lovett appeared in the *American Journal of Medical Sciences* for August, 1897. The name "habitual dislocation" refers only to those cases where dislocation occurs from causes too slight to displace the normal joint. Pathological conditions which are very variable have been found—depressions on the head of the humerus, or loose bodies in the joint; rents in, or laxity of the capsule; and rupture of muscles or tendons. Fractures or chronic non-suppurative inflammation are probable causes of some of the changes in the joint. Immobilisation of a joint for too short a period after a dislocation may prevent union of a rent in the capsule. A curious and unexplained fact is that a large proportion of the patients were epileptics. The writers have observed certain signs not heretofore recorded in patients subject to dislocation. There were drooping of the shoulder and notable atrophy of certain muscles—the coraco-brachialis, the triceps, the deltoid (especially the posterior part), the supraspinatus, the infraspinatus, the rhomboids, the levator anguli scapulæ, and the latissimus dorsi. The other muscles were not notably diminished. Examination by the fluorescope showed that the cathode rays penetrated the affected shoulder with more difficulty than the other, and that the head of the humerus was farther from the acromion, but it could be replaced by raising the elbow. Limitation of movement was present in all cases to a slight extent. In the absence of treatment the prognosis is bad, as the dislocations tend to become more frequent. The treatment consists of fixation combined with massage and exercise. If this fails after ten weeks' trial an operation is advisable. The arm is fixed by supporting it with a sling and holding it to the side with a swathe. After some weeks motion should be progressively allowed, together with massage and exercises for the muscles ordinarily affected. The treatment should be continued for at least three months. Faradaisation of the atrophied muscles is also a help. The writers recommend the following operation which has been perfectly successful in the two cases in which they performed it. An incision was made downwards and outwards from the coracoid process, following the line of the cephalic vein, to below the upper border of the insertion of the pectoralis major. The cephalic vein was drawn outwards, and the pectoralis major separated from the deltoid. The upper three-fourths of the insertion of the pectoralis major was divided, and the head and neck of the humerus came into view. A portion of the insertion of the subscapularis was divided. The arm was raised to a horizontal plane and the head pressed backwards to relax the capsule. The latter, which was apparently lengthened, was grasped with vulsellum forceps. Three sutures were inserted; a fold three-quarters of an inch in length and three-eighths of an inch in width was excised; the sutures were tied, and the wound was closed. No attempt was made to unite the partially divided tendons. Excision of the head of the humerus had been performed several times with good results; but it was only to be recommended when the joint presented such abnormalities as to demand it.

THE PECULIAR PEOPLE.

IT is a primary and self-evident proposition that the duty of the parents of a child who is ill is to procure medical advice for their offspring. The law looks on the neglect of this duty as tantamount to manslaughter. Unfortunately, in the case of the "Peculiar People" this line of conduct is negatived by the literal acceptance of a single text of the Bible, which is clearly meant to be read in connexion with the whole of Scripture, which abundantly recognises that they who are sick need a physician. Law is a legitimate means of correcting such absurd errors. The latest instance is that of a man, who allowed his child when suffering from lobular pneumonia to go from bad to worse, and finally to die. Mr. R. J. Carey, of Barking-road, made the post-mortem examination, and expressed the opinion that the child might have been saved by proper medical attention. The jury returned a verdict of "Manslaughter," and the father was committed to take his trial.

THE SANITARY CONDITION OF HIGH WYCOMBE AND WYCOMBE MARSH.

THE search-light of a Local Government Board inquiry was a few years since thrown upon the sanitary condition of High Wycombe, and, more recently, the village of Wycombe Marsh has been subjected to a similar investigation. As a result of all this, the conditions obtaining at both these places has become matter for public comment, and a portion of the lay press has recently uttered some strictures on the methods, or perhaps want of methods, of those who have been entrusted with the sanitary administration of High Wycombe. The two places referred to are situated in a Buckinghamshire valley draining into the Thames, High Wycombe being rather further removed from the Thames than is Wycombe Marsh. The sewage of the borough is conveyed by means of a main sewer, which is far from water-tight, to a sewage farm which is situated but a short distance from Wycombe Marsh. It was the intention in the first instance to chemically treat the sewage, but the volume of subsoil water finding its way into the sewers is so great that the sewage farm is altogether incapable of dealing with the diluted sewage arriving thereupon. As a consequence, the insufficiently treated sewage passes on to join the subsoil water beyond the sewage farm. This is, however, but half the story. It appears that neither the people of High Wycombe nor of Wycombe Marsh are provided with a proper water-supply, and this fact is particularly unfortunate for the people of the latter place, who draw their water from shallow wells sunk in the porous gravel of the district, into which much of the effluent from the High Wycombe farm escapes. Hence it happens that when enteric fever prevails in the borough, there is risk of the Wycombe Marsh wells becoming polluted; indeed, Dr. Buchanan, who recently investigated an outbreak of enteric fever at Wycombe Marsh, concludes that the evidence obtainable points to the contamination of the subsoil water as the cause of the outbreak. It is to be regretted that the extent of the prevalence of enteric fever in High Wycombe cannot be definitely arrived at, inasmuch as

Digitized by Google

the Wycombe councillors have but recently taken advantage of the facilities offered by the Infectious Diseases Notification Act; but certainly suspicion attaches itself to all authorities who are unwilling to make themselves cognisant of the dangers in their midst, and perhaps enteric fever may be found to be more or less endemic in High Wycombe. The town council is said to be at last bestirring itself in the matter of stopping the leaks in the sewers; but the amount voted for the purpose is not regarded by all as adequate, and it has yet to be proved that the sewage can be so treated as to afford any guarantee that pathogenic organisms arriving on the farm may not retain their virulence until they reach the subsoil water of Wycombe Marsh. The town councillors are naturally angry at their affairs being discussed in public, but it is their obvious duty at once to set their house in order; and it appears from the reports which we have read that a pure water-supply for the whole of High Wycombe and for Wycombe Marsh is not the least pressing question for the urban and rural district councillors to grapple with.

UNIVERSAL HYPERTRICHOSIS AND PREMATURE MENSTRUATION IN A CHILD.

THE following case, published by Lesser, appears in the July number of the *Revue des Sciences Médicales*. A girl, aged six years, who was not abnormal at birth, showed for the past two years a remarkable development of hair. The body, especially in the lower limbs, was covered with hairs more abundantly than in a very hairy man. The pubic hairs were more developed than in many adult females. There were whiskers on the face. The hair of the head was normal. Menstruation began at the age of three; it lasted six or seven days, and was profuse. In the following eighteen months it reappeared eight or nine times at almost regular intervals, and then ceased. The intelligence was advanced in a corresponding degree. The child's parents and elder brothers and sisters had normal development of hair, but two brothers, aged sixteen and twelve years, and next in age, had precocious beards. We may direct attention to one point. The case shows something more than precocious sexual development in the case of the hair. There is also production of male characteristics. Now, curiously, in the adult female this event is also associated with abnormal conditions of the genital organs.

THE SPAS OF SPAIN.

SPAIN possesses many mineral springs, but very few of them are at all well known in other countries. Amongst the few exceptions may be reckoned some aperient waters, the sulphurous springs of Panticosa in the Pyrenees near the French frontier, and also the alkaline waters of Vidago, termed the "Spanish Vichy." From the official statistics published by the Spanish Government[1] it appears that the total number of establishments is 169, and that they are scattered over forty-three different provinces. The total number of springs is 443, and those of Alhama (Zaragoza), Alhama Nuevo (Granada), and Fitero Nuevo (Navarra) yield the most copious supply of water. Amongst the hottest springs are those of Caldas de Montbuy in Barcelona (122° to 158° F.) and Archena in Murcia (131° F.). The spa of Panticosa in Huesca has the loftiest position, being about 5600 English feet above sea-level and nearly rivalling St. Moritz in altitude. Amongst strong sulphated waters the Spanish sources of Rubinat, Carabana, and Villacabras are tolerably well-known in other parts of Europe, especially in France; the aperient water of La Margarita, Loeches (Province of Madrid) is widely known in Spain, and is sold in bottles everywhere. The annual number of visitors is nearly 2500 at Caldas-de-Oviedo and at Montemayor (Caceres); some other spas, as Archena, attract considerably more. The greater proportion of the springs can be classed in either the common salt, simple thermal, or sulphurous groups.

THE SPECIAL CANADIAN SUPPLEMENT TO THE LANCET.

SOME copies of the Special Canadian Supplement to THE LANCET produced, printed, and published in Montreal on Sept. 3rd on the occasion of the meeting of the British Medical Association in Canada have reached us by the last mail. Such a publication is, we venture to think, a new departure in medical journalism. The supplement appears as a journal of forty-eight pages and contains the addresses of Dr. Roddick, Dr. Osler, and Mr. Mitchell Banks, a leading article, and editorial notes and comments upon the proceedings of the meeting, together with a (necessarily brief) report of the proceedings in the different sections.

THE CLOSURE OF WELLS LIABLE TO POLLUTION.

THE interpretation which the law usually places upon the provisions of Section 70 of the Public Health Act is far from satisfactory to the medical officers of health, who, in spite of a well being in a most dangerous environment, may be unable to effect its closure unless the water from it can be demonstrated by analysis to be polluted. That liability to pollution is a far more important point than the result of chemical or bacteriological examination is admitted by every epidemiologist, but, as a matter of practice, a given case must, as a rule, stand or fall according to the finding of the chemist at any given time. The decisions of the law have, however, a way of being modified in a remarkable manner, and when a legal position is obviously opposed to what may be called the common sense view the law tends to place an interpretation upon words and sentences in keeping with the spirit of the moment. This point was illustrated in an interesting fashion by a decision arrived at recently at the St. Albans divisional sessions, when the St. Albans rural district council sought closure orders against twenty-three owners of wells in the Bowling-alley, Harpenden. The contention of the council was that the whole of the area in which the wells in question were situated was pervaded by the enteric fever bacillus owing to the fact that the subsoil was permeated with infected excreta; furthermore, it was shown by chemical analysis that the water from the wells presented different degrees of organic pollution, although the wells were all supplied from the same source. It was urged, too, that the variations in the analyses during dry and wet weather showed the wells to be liable to intermittent pollution. For the defence it was argued that no chemical analyses had been produced, and that it must be proved before the Court that a well was actually polluted, and not that it was liable to pollution. The Bench, however, after much deliberation, decided to issue orders for closure, as they considered that the wells might prove dangerous in the event of a fresh outbreak of enteric fever taking place. Whatever may be the merits of this decision from a strictly legal standpoint, no epidemiologist is likely to quarrel with it. A locality where the excrement is placed in one pervious hole, and the drinking water taken from another but a short distance away, cannot be other than a dangerous one, and if the law does not enable wells which are thus situated to be closed the sooner an alteration is effected the better. Dr. Frank Dobbin, the deputy medical officer of health of St. Albans, is to be congratulated upon the manner in which he supplied the evidence in this case, and

Digitized by Google

although perhaps bacteriology will not altogether support some of the points taken up, there can be no doubt as to the general soundness of the position.

THE SANITARY INSTITUTE.

THE twenty-fourth London course of lectures and demonstrations arranged by the Sanitary Institute for the instruction of sanitary officers and students will commence on Sept. 27th and will conclude on Nov. 27th. The various subjects will be dealt with in a course of eighteen lectures, given by well-known authorities, and will be illustrated by diagrams, drawings, models, and lantern slides. The lectures will include the subjects scheduled for the examinations of the institute. In connexion with the lectures there will be inspections and demonstrations, which will include visits to disinfecting stations, dairy premises, municipal depôts, artisans' dwellings, waterworks, common lodging houses, sanitary works in progress, and refuse and sewage disposal works. Practical demonstrations of meat inspection and diseased meat will also be given. The fee for the course is two guineas; a student who enters his name for one of the examinations of the institute at the time of taking his ticket for the lectures can have one guinea carried forward towards his fee for examination. The museum of sanitary appliances and the library will be open free during September, October, and November to students attending the course. The introductory lecture on the Outcome of Sanitation, will be delivered by Dr. Louis Parkes, medical officer of health of Chelsea, on Monday, Sept. 27th at 8 P.M., and the remainder of the series will be given by other lecturers on subsequent Mondays and Thursdays at the same hour. Application should be made to Mr. E. White Wallis, secretary of the institute, Parkes' Museum, Margaret-street, Regent-street, W.

NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

THIS school, which is exclusively for legally qualified practitioners, undergraduates not being admitted on any conditions, was last year attended by 513 matriculates. The Post-Graduate Hospital is now one of the largest in New York City, having 183 beds. During the past winter the average number of beds occupied at one time was 150. The accommodation is such that practitioners may witness several important operations each day without leaving the building and may also see a large number of patients in the dispensary. The teaching of the school is entirely clinical or demonstrative. In some departments—diseases of the eye and ear, nose and throat, and diseases of women—arrangements are made by which the class may attend the service at other hospitals, as well as the clinics in the Post-Graduate School itself. The hospital is open during the entire year. The school year is divided into two distinct but continuous terms. The autumn and winter courses begin on Sept. 20th and end on June 1st, during which period the fees are $150 for a term of twelve weeks, and $100 for a term of six weeks. During the summer session, the fee for the general course is $30 a month, or $95 for the whole term, from June 1st to Sept. 20th. The school and hospital are in the same building, situated at the corner of Second Avenue and Twentieth-street, New York. They are not private institutions, but are a chartered medical college and hospital forming a part of the university system of the State. A monthly journal, called *The Post-Graduate*, is published by the directors of the school and hospital.

HER MAJESTY THE QUEEN has decided that a public exhibition of the gifts and addresses presented in commemoration of her sixty years' reign shall be held in the Imperial Institute, probably about the middle of October. Half the proceeds is to go to the Prince of Wales's Hospital Fund.

WE learn, just as we are going to press, that Mr. Victor Horsley has consented to be nominated for the vacant seat as a Direct Representative on the General Medical Council.

DR. A. E. SANSOM, President of the Medical Society of London, has been elected an honorary member of the Therapeutical Society of Moscow.

Pharmacology and Therapeutics.

CELANDINE IN CANCER OF THE FACE.

DR. KRAINSKI, writing in the *Russian Ophthalmic Review*, records four cases of malignant disease of the eyelids and face in which he employed the celandine treatment. In two of the cases the neoplasms completely disappeared. In the other two there was distinct improvement, but the cases could not be followed up and so the ultimate result cannot be stated. The time required for the destruction of the tumour was not more than a fortnight. Several injections were made in the sound tissue bordering upon the neoplasm. They were composed of equal parts of extract of chelidonium, sterilised water, and glycerine, four to eight minims of the mixture being introduced at a time. In addition to these a 50 per cent. solution of the extract in glycerine was applied externally twice a day and a dressing put on. The celandine did not affect the healthy tissues and was well tolerated by the conjunctiva. There was some pain for a few hours, and in two cases pyrexia. There was, too, a good deal of swelling around the tumour, and in one case suppuration at the situation of the punctures. Dr. Krainski has also given celandine internally in cases of cancer of internal organs where operation was impossible. A further paper is promised on this subject.

SALICYLATE OF METHYL IN JOINT TROUBLES OCCURRING IN THE COURSE OF FEVERS.

According to Dr. Roger, professor *agrégé* of Paris, the joint pains which sometimes give a good deal of trouble in the course of scarlet and other eruptive fevers may be very successfully treated by the application of about half a teaspoonful of salicylate of methyl to the affected joint which is then bound round with a compress and a piece of waterproof tissue. This is repeated night and morning, and usually has a rapidly beneficial effect.

WHEN IRON IS USEFUL IN ANÆMIA.

It is well known that iron, though strongly indicated, is often not well borne by anæmic and chlorotic patients. According to some recent observations by Dr. Buzdygan the success of iron in these cases depends upon the amount of acid in the contents of the stomach. He found that when there was hyperacidity the administration of three grains of reduced iron, subcarbonate or iodide of iron, only increased the amount of acid and aggravated the troubles usually present in these cases—pyrosis, feeling of weight in the stomach, nausea, and vomiting. When, on the other hand, the contents of the stomach were alkaline or less acid than usual the administration of iron was always well borne, and, indeed, induced a more abundant secretion of hydrochloric acid. In the former class of case, then, the proper line of treatment is evidently first of all to correct the hyperacidity and then to prescribe the ferruginous preparation decided upon.

NAPHTHALAN.

A series of observations has been made in Professor Finger's out-patient department by Dr. Pezzoli on a new preparation named naphthalan which appears to combine the therapeutical properties of tar with those of naphtha. It is a dark-brown unctuous substance with scarcely any smell and a melting point of about 70° C. When used as an ointment it leaves no stain on the patient's linen after it has been washed. It is very useful in various forms of eczema, sycosis, and common psoriasis, as well as in parasitic affections such as ringworm and scabies. It should be used with a certain

Digitized by Google

degree of caution, as if rubbed in too energetically it is liable to produce some folliculitis of the same nature as tar-acne. It was tried in 42 cases of eczema and appeared to be of value in all stages, which renders it a very convenient preparation for general or out-patient practice. Excellent results were obtained in all the 15 cases of impetigo contagiosa in which it was prescribed. In scabies three applications were found to be sufficient.

EFFECT OF THYREOIDIN ON THE ASSIMILATION OF FAT.

Dr. Tikanadze, of St. Petersburg, has made a series of careful investigations as to the exact effect of Merck's thyreoidin on the assimilation of fat in healthy subjects, comparing the action of this with that of fresh calves' thyroids. The quantity of thyreoidin given was 0·24 gramme, and that of the fresh gland 2·12 grammes, per diem. He found that the quantity of fat assimilated diminished to the extent of from 1·33 per cent. to 4·43 per cent., the thyreoidin producing a more marked fall than the fresh gland. In all cases the quantity of urine excreted was increased. The body weight fell one or two kilogrammes during the six days which were devoted to the experiment, which he believed to be due to the lessened assimilation of fat and the increased excretion of urine and nitrogenous metamorphosis.

ORTHOFORM, A NEW LOCAL ANALGESIC.

It has been found by Dr. Einhorn and Dr. Heintz, of Munich, that the compound methylic ether of amidoxybenzoic acid is possessed of remarkable anæsthetic, or rather analgesic, properties when locally applied. To this substance the name of "orthoform" has been given. It is a white crystalline powder without taste or smell and it dissolves slowly in water. Unlike cocaine it is non-poisonous, and though its analgesic action is somewhat tardy in showing itself it is very much more persistent than that of the older drug. This prolonged effect is very valuable in the case of painful sores or wounds, more especially in burns and in fissures of the lips or nipples. It may be applied to mucous membranes in powder or as an ointment. Orthoform diminishes the secretions and is antiseptic. Its local action may be taken advantage of for internal administration in painful ulcers of the stomach, whether these are or are not of a malignant nature. The hydrochlorate, which is very soluble, is too acid for use as a hypodermic injection or for applying to the eye, but may be employed for internal administration or for urethral injections. In a case of gleet a 10 per cent. solution was well borne and gave relief from pain for many hours, but it provoked severe reaction in a case of acute gonorrhœa—here, however, the discharge ceased completely in four days. As to the dose, a saturated solution of orthoform in water at ordinary temperatures is suitable for local application, and seven and a half grains of the hydrochlorate, or even more, may be given internally several times a day without any inconvenience. It appears therefore that this substance and its salt may be considered entirely non-poisonous. Indeed, in a case of carcinoma of the face more than 700 grains were locally applied during the course of a week without any injurious effect, great relief being obtained.

REPORTS OF LUNATIC ASYLUMS FOR 1896-97.

Joint Counties Lunatic Asylum, Caermarthen (1896).—During the year there were 137 cases admitted, 29 recoveries, and 50 deaths. The number of post-mortem examinations made was 48; from a pathological point of view this is a very satisfactory record. It is abundantly evident that in the majority of the lunatic asylums throughout the country increased attention is now being paid to pathological work, and in many institutions facilities are provided for the prosecution of original research. In this way much important information of scientific value must accumulate—information too valuable to be buried away in case-books and records and thereafter lost sight of. It is a moot point whether the pages of asylum reports are utilised to the best advantage, and if some space were allotted to the publication of any interesting pathological data garnered during the year the value of these reports would undoubtedly be materially enhanced. In its clinical aspect Dr. Goodall's report is decidedly above the average, and he alludes to several topics which have recently attracted attention. His remarks on the influence of heredity in the causation of insanity, and his powerful advocacy of a systematic examination for the detection of stigmata amongst the insane and also among criminals are deserving of more than passing notice. He suggests the erection of a separate institution for the idiot and imbecile class in the principality, and emphasises the benefits that accrue from the early medical treatment of insanity.

Dorset County Lunatic Asylum (1896-97).—Dr. Macdonald's reports always afford fresh and invigorating reading, and his account of the past year's work forms no exception to the rule. A feature in the management of this asylum is the open-door system. With the exception of the door which divides the two sexes no door on either side is locked, and the patients on each side have free liberty of movement to other wards and to the grounds. The admissions numbered 213, the recoveries 46, and the deaths 42. Dr. Macdonald calls attention to the large number of first admissions amongst the county cases, and states that each year there is a greater number of cases which may be termed instances of early mental confusion and instability. For this condition of things he is inclined to think that the educational code is not altogether free from blame. In many districts no special provision exists for the education of children who are below the average in intelligence, consequently a percentage of boys and girls are forced and crammed beyond their natural abilities, with the result that permanent harm ensues. Regarding the causation of insanity the influence of hereditary predisposition is specially noted, and some trenchant remarks are made concerning the evil consequences of matrimonial contracts among the mentally weak and tainted members of the community. The Commissioners in Lunacy report very favourably on the management and condition of the asylum, which is now lighted by electricity and warmed throughout by artificial heat.

St Andrew's Hospital for Mental Diseases, Northampton (1896).—Structural alterations to a considerable extent have been in progress. The history of the institution has been uneventful during the year and the working of the hospital has been satisfactory in every respect. The Commissioners in Lunacy express their satisfaction with the state and surroundings of the patients, and speak with approval concerning the large number of inmates who are induced to work. The percentage of recoveries to the total number of admissions was 46 90; the death-rate was exceptionally low, being 3·59 per cent. of the average daily number resident.

Isle of Wight County Asylum (1897).—First Annual Report).—This asylum, which is situated near the town of Newport, was opened for the reception of patients in July, 1896. The present accommodation provides for 260 patients, and in addition a detached block for 50 private patients has been constructed. The water-supply is from a deep well, and it has been reported on in favourable terms. The lighting is electrical, worked by dynamos on the spot. The wards and passages are heated by hot-water pipes. The Lunacy Commissioners were favourably impressed with the condition of the asylum, and they view encouragingly the practice of affording parties of patients extended exercise beyond the asylum grounds, believing it to be of great importance in the treatment of the insane. The anxious and onerous duty of opening the new asylum was accomplished in a manner which reflects great credit on the administrative skill of Dr. Shaw, the medical superintendent.

Surrey County Lunatic Asylum, Brookwood (1897).—Overcrowding with its attendant evils has brought this institution into a somewhat unsatisfactory condition. The asylum provides accommodation for 1050 patients, but for the past three years the number of inmates has averaged 1077, and on several occasions the population has for a short time been over 1100. The situation demands the immediate attention of the asylum committee and the county authorities. There is imperative and immediate need for the enlargement of the existing institution, or for the building of a new asylum. The difficulties of the management are great and numerous, and it is not surprising that Mr. James E. Barton, the medical superintendent, reports the general health as only fairly good. He states that the over-pressure has been especially felt on the female side, where, in addition to a large number of old and feeble patients, there are many cases requiring special supervision and also many turbulent and violent women. During the year there were 288 admissions, 91 recoveries, and 109 deaths. The death-rate amounted to

Digitized by Google

10·06 per cent. of the daily average number resident. The services of an additional assistant medical officer are obviously required.

Hereford County and City Lunatic Asylum (1897).—Owing to lack of accommodation it was found necessary to make a conditional closing order, restricting the number of admissions. Before having recourse to this stringent measure, inquiries were made as to the feasibility of boarding out a number of imbeciles and harmless dements with relatives and others. Many of the friends, however, appeared disinclined to receive their insane relatives, and the accommodation offered by those who were willing was generally found to be unsuitable. Owing to these and other causes the project had to be abandoned. During the year 70 patients were admitted, 40 recovered, and 23 died. Nearly one-sixth of the male admissions suffered from general paralysis, a proportion much above the average. The general health of the patients was good. Influenza, which has been more or less endemic since 1890, was the main cause of ill-health. In connexion with this disease Mr. C. S. Morrison records a rather curious fact. He states that the influenza poison had the effect in many instances of bringing the deluded and chronic maniac into a more introspective frame of mind, and from being wild and troublesome the patient subsided into a more orderly, if somewhat moody, individual. It would be interesting to know whether the mental change so produced was permanent or only temporary in character, and further information on the point would be welcome. It is well known that all acute bodily diseases have the effect of more or less modifying the symptoms of mental derangement, but it is generally understood that in the majority of cases the sensory disorder resumes its sway as the physical symptoms subside.

Newcastle-upon Tyne City Lunatic Asylum (1896).—The average daily number resident during the year was 467. The admissions numbered 137, the recoveries 49, and the deaths 54. Amongst the admissions there were 26 cases of general paralysis, 4 epileptics, 8 congenital imbeciles, and 11 cases of senile insanity—all incurable cases. In 40 instances the causation of insanity was attributed to moral factors—viz., domestic trouble, adverse circumstances, and mental anxiety; intemperance in drink caused mental disorder in 50 instances; hereditary predisposition was ascertained in 29 cases. The death-rate was high, but this is hardly to be wondered at, considering that twenty patients died from general paralysis, and nine from phthisis. The report of the Commissioners in Lunacy indicates that Dr. Callcott manages his asylum with care and ability. They state that they found all parts of the asylum in excellent order, the day-rooms bright and cheerful, and facilities for the amusement of the patients plentiful.

Kirklands Asylum (1897).—The work of the asylum has been carried on in a quiet and uneventful manner. The health of the patients has been on the whole excellent. There were 22 entries in the Register of Restraint and Seclusion referring to the restraint of 6 patients at various times and for various reasons. Dr. Skeen thinks that restraint is sometimes beneficial, and bases his opinion on the following grounds. It ensures rest and warmth at night; it obviates the necessity for the employment of sedative drugs, which are often injurious and can only be used with extreme caution in those old and debilitated persons who constituted the class of patients to whom restraint at night was applied; further, the judicious use of restraint also relieves the nursing staff, especially at night, of a vast deal of anxiety without in any way reducing the responsibility, and therefore without inducing a tendency to carelessness and inattention towards the patients under their care. In these progressive days such opinions may appear somewhat heterodox, but there can be no doubt that there is something to be said in favour of Dr. Skeen's views. The admissions were 63; 30 patients recovered, and 18 died. The Lunacy Commissioners (Scotland) comment favourably on the general management of the asylum.

Barony Parochial Asylum, Lenzie (1896).—In a short report Dr. Blair states that of 313 patients admitted, the causation of insanity in 70, or 22 3 per cent., was ascribed to organic changes in the cerebro-spinal system, and of these nearly 11 per cent. were general paralytics and 6 per cent. epileptics. Alcoholic excess was ascertained to be the cause in 17·6 per cent., which is about 5 per cent. more than the records of late years. The extension and improvements which have been effected within recent years make this asylum one of the best equipped institutions for the insane in Scotland.

THE VACANCY IN THE GENERAL MEDICAL COUNCIL.

FOR the information of those who may intend to seek the suffrages of the profession for the seat on the General Medical Council as a Direct Representative, rendered vacant by the resignation of Dr. Rentoul, we would point out that procedure is regulated strictly by the Act of Parliament. The first step has already been taken by the President, who has notified the vacancy, and the rest follow as a matter of course. They are:—

Notice of election to be published	Sept. 10th.
Precept to be issued by returning officer	Sept. 25th.
Final day for receipt of nomination papers ...	Sept. 27th.
Meeting of the English Branch Council to receive precept	Sept. 28th.
Issue of voting papers	Oct. 2nd.
Last day for return of voting papers...	Oct. 9th.
Counting of votes	Oct. 11th.
Meeting of Branch Council to certify result of election	Oct. 15th.
Declaration of poll by the returning officer	Oct. 15th or 16th.

We have received the following addresses from candidates:—

TO THE REGISTERED MEDICAL PRACTITIONERS OF ENGLAND AND WALES.

GENTLEMEN,—By the resignation of Dr. Rentoul a seat in the Medical Council has quickly become vacant, and is to be filled as the will of the electorate may determine. I beg leave, therefore, to represent to you my readiness to stand as a candidate for the honour of your suffrages, and to state that the principles I ventured to lay before you previous to the last election are those which I would now submit as mine. They are detailed in THE LANCET of Oct. 31st last year on page 1253; and as bearing upon the whole of the paragraphs there written I would say that the Direct Representatives should act with the other members of the Council in full confidence that all are engaged in seeking the welfare of the profession; but at the same time he should realise the special business which belongs to him as the representative of the general practitioner, and be ready to act according to the dictates of common sense, as the opportunities for his intervention may occur.

The number of gentlemen who availed themselves at the last election of their privilege as voters was unusually small; and this fact gave opportunity to those who are not friendly to the representation of the general practitioner upon the Medical Council to comment adversely to our interests in this particular. It will be a pity if these comments should appear justified on the present occasion, for while the whole profession of medicine has greatly advanced as a science and an art, to the benefit of the individual, so now it is surely moving, by the force of its intrinsic national importance, towards that dignified position in the State which farseeing men have in the past predicated for it; and who are they that should show interest in this movement of our common profession if the bulk of us who practise it do not? The answer should be given in a good poll next month.

The gentlemen who stood so well by me last November may see fit again to support my candidature. To them, therefore, as well as to those others who will do me the like honour, I would submit that anything approaching an active candidature otherwise than through the medical press is entirely beyond my power. Hence I would respectfully ask them to acquit me of any discourtesy in not communicating with them directly, and to generously use their influence for securing votes in favour of the principles I have enunciated. Because if each voter will in his goodness consider himself a centre for influencing others, success is to that extent rendered, if not absolutely certain, at all events more likely.

In conclusion, I beg to state that if I be elected your representative the tone of my influence at the Council Board will be the tone of this address. But if I be not elected, in whatever place my name may appear, I shall be ready to believe that the choice of the electorate had fallen upon a man whose sentiments are not less worthy than those which I myself hold. In this assumed case, however, I should add that his capacity and his willingness to serve your interests would probably be in no way greater than my own.

I am, Gentlemen, your faithful servant,
E. DIVER, M.D. St. And., M.R.C.S. Eng.

TO THE REGISTERED MEDICAL PRACTITIONERS OF ENGLAND AND WALES.

Sept. 14th, 1897.

LADIES AND GENTLEMEN,—I beg to offer myself as a candidate for the present vacancy amongst the Direct Representatives on the General Medical Council. I am encouraged to take this step by the fact that at the election last November I polled 4082 votes, and was therefore at the head of the unsuccessful candidates, and that I have now received the assurance of the support of the Incorporated Medical Practitioners Association and of other medical bodies. It is my duty once more briefly to state my views on the crucial questions of the day in their relations to the General Medical Council.

I venture to traverse the opinion which has been influentially expressed that the Midwives Bill does not concern the Council. To my mind, the fact that the Government have sought the opinion of the Council on the matter proves that the question is one of vital importance to the medical profession, and therefore deserves the most careful attention of its governing body. From this it follows that the opinions

Digitized by Google

of the great body of the profession which is strongly opposed to midwives legislation shall be represented on the General Medical Council.

If elected I should also advocate:—

1. Reform of the Medical Acts so that the Council should be, at any rate, in a larger proportion than at present, elected by, and representative of, the profession generally.

2. The assimilation of the Acts governing the profession more nearly to those which govern the legal profession. By this means more power would be given to the General Medical Council to protect the public against quacks and unqualified practitioners.

3. The raising of the standard of entrance examination and the establishment of one conjoint compulsory examination for each division of the United Kingdom.

Finally, if you do me the honour to elect me as one of your Direct Representatives, I would devote my whole energies to fulfil the trust reposed in me. I have the honour to be, ladies and gentlemen,

Your obedient servant,

GEO. JACKSON, F.R.C.S. Eng.,

Vice-President and Ex-President of the Incorporated Medical Practitioners Association; Vice-President and Ex-President of the Devon and Cornwall Branch of the Incorporated Medical Practitioners Association.

OUR FRONTIER TROUBLES IN INDIA.

THE Government of India has been subjected to much adverse criticism for its want of promptitude in not advancing up the Khyber and at once recovering the positions captured by the Afridis. No doubt a decrease of British prestige attended our loss of Lundi Kotal and Ali Musjid, although these were held by native levies only. But there are other points to be considered besides promptitude of action; possible failure has to be guarded against, and means have to be taken to ensure that the force is strong enough and sufficiently provisioned to hold the posts when captured as long as required. It is comparatively easy under the present system of military organisation and administration in India to mobilise and concentrate a force on any given point of the Indian frontier, but for mountain warfare against the Afridis and other tribes a large amount of animal transport is needed, as well as an abundance of food and stores to maintain an army in the field until we can ensure sufficient security for future peace before the forces are withdrawn. Moreover, the season has hitherto been bad as regards the health of the troops of any expeditionary force. Up to the middle of September the heat in the valleys is very great, but a month later there is a great change in this respect: the valleys are much cooler and the mountains are very cold, and the climate is much more favourable for our operations. The strength of the forces under the respective commands of General Blood and General Elles should make it pretty certain that the rising of the Momands will soon be overcome, and the punitive expedition to Tirah, the centre of the Afridi territory, will deal with and crush the power of the Afridis. We do not at all believe that a combined and simultaneous action among *all* the tribes on the north-west frontier can take place, but the extent and general character of the rising on this occasion indicate that there must be some common cause in operation for the widespread feeling that undoubtedly exists. This is attributed at Peshawar to the strong resentment that is felt amongst the tribes against our occupation of the Swat Valley, which is being interpreted as annexation by the mullahs. Be this as it may, the time has now come for the rising to be forcibly put down with as little delay as practicable. It already looks as if there were a combination of the Oraksai and Afridi tribes—a combination which is new in border history. There has of late been a good deal of sharp fighting in various directions, and the hostile tribes have made several resolute attacks on our forces. Anyone looking at a map of this mountainous and nearly sterile country will easily appreciate its obstacles and difficulties as a scene for military operations and can form some idea of the amount of animal transport required for the conveyance of ammunition and warlike stores and commissariat supplies. The supply of water for the troops during the hot season will also prove a difficulty. The expense attending this frontier warfare is very great, and in the present embarrassed state of Indian finance this is greatly to be deplored. We are glad to learn that the wounded are doing well and that the health of the troops engaged is good, that the pluck and endurance of the native and European troops are admirable, and that the great mass of the population in India is well affected to British rule. That there will be a successful ending to the present state of affairs may be regarded as certain, but it is also certain that it will cost a great deal of money and necessarily much loss of life to bring this about.

The extent of the rising and the nature of the country will probably require a large force divided into different columns operating in different directions, with, of course, a common object in view, and it may possibly take a longer time to achieve complete success than many people imagine. The diseases to which the troops will be liable will be various forms of fever—mainly of a malarious type—and dysentery. Cases of enteric fever among the British troops will also occur, but it is scarcely likely that this fever will prevail to any extent during the cold season. Among the native troops and the native followers malarious fever, dysenteric-diarrhœa, and pulmonary diseases are almost sure to prevail; but as regards the latter much may be done to prevent their occurrence by an adequate supply of clothing and blankets, the avoidance of overcrowding, and the provision of plenty of food. During the last Afghan wars there was an enormous amount of sickness and mortality among the camels and baggage animals. Mules and ponies are hardier and much superior to camels as transport animals for expeditions of this kind.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the Sanitary Condition of Swanage, by Dr. S. W. WHEATON.—Swanage is one of a by no means small number of watering-places which profess to attract to themselves persons who are seeking health as well as pleasure, but which persistently maintain conditions that are not only a constant risk to health but which actually amount to obvious nuisance. The inspection dealt with in the report now before us is the third which the Local Government Board have found it necessary to make at Swanage within a comparatively brief period. In 1886 inspection became necessary by reason of a severe epidemic of enteric fever; in 1893 Swanage was one of the suspicious places in England which were especially selected for a visit when the country was exposed to the European prevalence of cholera; and now, again, in 1897 we have another visit and report by reason of the frequent complaints which are made as to the nuisances prevalent in the place and as to the maladministration of the urban district council. The main grievance arises in this way. The town borrowed £6000 in 1893 to provide sewers converging to an outfall sewer discharging into the sea below low-water mark north of the southern headland bounding Swanage Bay. But, having performed one part of their undertaking, the urban council seemed to think they had done enough. The consequence is that the new sewers have been turned into an old culvert discharging on the foreshore, that the old sewers have not been removed, that many dwellings have not been connected with the new system, that in places the old and new sewers run side by side, the old one receiving sewage and the new one none, and that, to quote Dr. Wheaton, "the £4500 spent have so far been of very doubtful benefit" The bathing places, to which visitors of both sexes are attracted, are also stated to lie "between two points of discharge for sewage." But these are not all the insanitary features of Swanage. Vault privies still seem fairly general notwithstanding the money spent on sewers, and they are so constructed that there is always more or less escape of their contents into the surrounding soil. The cleansing of these structures and the renewal of ashpits is left to occupiers, unless they apply to the urban council, who then make a charge for the work. This we believe to be absolutely illegal. The Public Health Act of 1875 only recognises two methods—one in which the work is undertaken by, and at the cost of, the occupiers; and the other in which it is undertaken by the sanitary authority at the cost of the ratepayers. But further, the Swanage Urban Council will not even learn by experience. In 1886 the outbreak of typhoid fever was due to milk, and they were urged by the Local Government Board

Digitized by Google

to draw up regulations to control their cowsheds and dairies; but they have done nothing of the sort, and "the condition of the majority" of the cowsheds "is filthy." There are other matters to which we might advert; but we have said enough to indicate the imperative need for some further visit to, and report on, Swanage early next spring; so that those who seek health and wish to avoid nuisance and risk of danger to health may be advised where to seek it in the autumn. If the inhabitants of a district profess to cater for the public health—and Dr. Wheaton says the majority are here engaged in supplying the wants of visitors—they have a duty towards the public; and it is of the utmost importance that this should be understood.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Birkenhead Urban District.—Dr. Sydney Marsden advocates that the City of Birkenhead shall, under the provisions of the Shop Hours Act, 1892, reduce the hours of barmaids to seventy-four per week. He states that in some hotels more than a hundred hours per week are exacted from these persons. The low standard taken up by the Somerset House authorities as regards milk is matter for Dr. Marsden's comment; he thinks that the excuse so often urged that the poor quality of the milk is due to the fact that the cow is out of condition should not be allowed the weight so often attached to it. Even if the excuse be true, the cow's milk should, Dr. Marsden urges, not be sold, and the cow should be withdrawn from use until its health be improved. Under the heading of "Death-rates of insanitary areas" the following table, which speaks for itself, is given:—

Average for 1886–93.

—	Population.	Death-rate per 1000.	Zymotic death-rate.
Whole Borough...	99,688	19·8	3·1
Area No. 1	106	72·6	13·2
,, ,, 2	80	42·5	10·0
,, ,, 3	112	63·3	15·0

The population of the area is obviously a small one, and it would be interesting to know the age-distribution. From an analysis of the figures and of the causes of death Dr. Marsden thinks that the effect of living in these insanitary areas is more especially to lower the general system of the individual. It is certainly necessary to be very cautious in drawing conclusions from the death-rates of insanitary areas, as it is to such areas that the helpless and old, and the poor with large families, are drawn by the force of circumstances, the death-rates often being rather an expression of social conditions than the direct effect of an insanitary area.

Nottingham Urban District.—Enteric fever is unduly prevalent in Nottingham, and Dr. Philip Boobbyer is by no means content that it should be so. Nottingham is clean, well-sewered, and is provided with a supply of pure water. Why, then, should it have had its enteric fever death-rate during 1896 exceeded by only three of the other great towns—i.e., Sunderland, Bolton, and Wolverhampton. Upon this subject of excessive prevalence of enteric fever Dr. Boobbyer is preparing a special report, but in the meantime he furnishes certain figures in his current annual report which are instructive and, by virtue of the number of years to which they have reference, valuable. For each year from 1887 to 1896 inclusive there has been an altogether exceptional incidence of enteric fever upon houses furnished with privies as compared with those furnished with pail closets and water-closets, the rate on the pail houses being much higher than that on the houses with water-closets. The same remarkable incidence has obtained in each year during the period referred to, and the total figures for the ten years are thus summed up: (*a*) pail-closet houses, one case of enteric fever in 120 houses; (*b*) midden-privy houses, one case of enteric fever in 37 houses; and (*c*) water-closet houses, one case of enteric fever in 558 houses. These interesting and, as has been observed, constant results are not to be explained away by the criticism that enteric fever may be expected to be exerting its greatest influence on the poorer property provided with midden-privies and with pail-closets. The privies seem to be very scattered and not confined to any one part of the borough, some of them being attached to a good class of houses. Similarly water-closet houses are not confined to the better parts of the town. It seems, too, that there is a marked tendency on the part of enteric fever to spread in houses provided with such closets as retain the excrement on the premises. The pails used in Nottingham are constructed of wood, and Dr. Boobbyer is of opinion that their influence for evil in the matter of enteric fever is due to the absorbent character of the wood; steel drums should, he thinks, be used in the absence of a water-carriage system.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6795 births and 4089 deaths were registered during the week ending Sept. 11th. The annual rate of mortality in these towns, which had declined in the four preceding weeks from 29·5 to 20·7 per 1000, further fell last week to 19·4. In London the rate was 16·3 per 1000, while it averaged 21·5 in the thirty-two provincial towns. The lowest death-rates in these towns were 8·2 in Halifax, 9·5 in Croydon, 11·3 in Cardiff, and 11·4 in Swansea; the highest rates were 26·9 in Liverpool, 28·5 in Hull, 31·1 in Wolverhampton, and 35·3 in Preston. The 4089 deaths included 945 which were referred to the principal zymotic diseases, against 1783 and 1272 in the two preceding weeks; of these, 671 resulted from diarrhœa, 78 from whooping-cough, 65 from measles, 52 from "fever" (principally enteric), 48 from diphtheria, and 31 from scarlet fever. The lowest death-rates from these diseases were recorded in Swansea, Halifax, Cardiff, and Derby; and the highest rates in Sheffield, Leicester, Salford, Hull, and Preston. The greatest mortality from measles occurred in West Ham, Manchester, Oldham, and Preston; from scarlet fever in Bolton; from whooping-cough in Liverpool and Oldham; from "fever" in Sunderland; and from diarrhœa in Leicester, Salford, Preston, Leeds, Hull, and Newcastle-upon-Tyne. The 48 deaths from diphtheria recorded last weeks in the thirty-three towns included 25 in London, 4 in Birmingham, 4 in Leicester, and 3 in Liverpool. No death from small-pox was registered during the week under notice in any of the thirty-three towns; and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital which had been 3400, 3448, and 3528 at the end of the three preceding weeks, had further increased to 3579 on Saturday last, the 11th inst.; 376 new cases were admitted during the week, against 340, 356, and 371 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 102 and 116 in the two preceding weeks, were again 116 last week, and were 37 below the corrected average. The causes of 48, or 1·2 per cent., of the deaths in the thirty-three towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Nottingham, Bradford, Leeds, and in twelve other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Leicester, and Liverpool.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·6 and 18·1 per 1000 in the two preceding weeks, rose again to 18·3 during the week ending Sept. 11th, but was 1·1 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·3 in Paisley and 15·3 in Perth, to 19·9 in Edinburgh and 22·0 in Greenock. The 545 deaths in these towns included 63 which were referred to diarrhœa, 15 to whooping-cough, 7 to diphtheria, 5 to scarlet fever, 5 to "fever," 2 to measles, and 1 to small-pox. In all, 98 deaths resulted from these principal zymotic diseases, against 137 and 127 in the two preceding weeks. These 98 deaths were equal to an annual rate of 3·3 per 1000, which was 1·2 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had declined from 147 to 84 in the three preceding weeks, further fell to 63 last week, of which 29 occurred in Glasgow, 14 in

Digitized by Google

Edinburgh, and 7 in Dundee. The 15 deaths from whooping-cough also showed a further decline from the numbers recorded in recent weeks, and included 9 in Glasgow and 2 in Edinburgh. The fatal cases of diphtheria, which had been 1 and 4 in the two preceding weeks, further increased to 7 last week, of which 3 occurred in Glasgow, 2 in Edinburgh and 2 in Aberdeen. The deaths from scarlet fever, which had risen from 5 to 10 in the three preceding weeks, declined again to 5 last week, of which 2 were recorded in Glasgow and 2 in Edinburgh. The 5 deaths referred to different forms of "fever" included 3 in Glasgow, where the fatal case of small-pox also occurred. The deaths from diseases of the respiratory organs in these towns, which had been 78 and 69 in the two preceding weeks, rose again to 78 last week, and slightly exceeded the number in the corresponding week of last year. The causes of 30, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·0 and 23·1 per 1000 in the two preceding weeks, declined again to 22 4 during the week ending Sept. 11th. During the past ten weeks of the current quarter the death-rate in the city has averaged 23·4 per 1000, the rate during the same period being 20·5 in London and 18·2 in Edinburgh. The 150 deaths registered in Dublin during the week under notice showed a decline of 5 from the number in the preceding week, and included 28 which were referred to the principal zymotic diseases, against 39 and 33 in the two preceding weeks; of these 16 resulted from diarrhœa, 4 from "fever," 3 from diphtheria, 3 from whooping-cough, and 2 from scarlet fever. These 28 deaths were equal to an annual rate of 4·2 per 1000, the zymotic death-rate during the same period being 2·6 in London and 3·7 in Edinburgh. The fatal cases of diarrhœa, which had been 32 and 25 in the two preceding weeks, further declined to 16 last week. The 4 deaths referred to different forms of "fever" exceeded the number recorded in any recent week. The fatal cases of diphtheria, which had been 2 and 4 in the two preceding weeks, declined again to 3 last week. The 3 deaths from whooping-cough corresponded with the number recorded in the preceding week. The 150 deaths in Dublin last week included 42 of infants under one year of age and 18 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from those recorded in the preceding week. One inquest case and 2 deaths from violence were registered; and 50, or one-third, of the deaths occurred in public institutions. The causes of 13, or nearly 9 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-CAPTAIN WRIGHT embarks shortly for Malta. Surgeon-Major Beevor is held in readiness for service in India. Brigade-Surgeon-Lieutenant-Colonel J. Macnamara is ordered to embark for Malta in the transport *Avoca*. Surgeon-Captain Tate is ordered to join at Woolwich for duty. Surgeon-Major Smythe and Surgeon-Captain Tatham embark at the Royal Albert Dock on board the transport *Avoca*.

Surgeon-Lieutenant-Colonel Aylmer E. Hayes, D.S.O., retires on retired pay. Surgeon-Major Robert C. Gunning to be Surgeon-Lieutenant-Colonel.

Royal Horse Guards: Surgeon-Captain Horatio R. O. Cross, from 1st Life Guards, to be Surgeon-Major, vice H. Mitchell, retired.

Grenadier Guards: Surgeon-Major Charles R. Kilkelly, M.B., from Army Medical Staff, to be Surgeon-Major, vice W. C. Beevor, M.B., who exchanges.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of the under-mentioned officers are replaced at the disposal of the Military Department: — Surgeon-Captain Brogden, A.M.S., Surgeon-Captain Bray, A.M.S., Surgeon-Captain Clark, A.M.S., Surgeon-Captain Boyle, A.M.S., Surgeon-Lieutenant Evens, A.M.S., Surgeon-Lieutenant Milner, A.M.S., and Surgeon-Lieutenant Rainier (Bengal). The services of Surgeon-Captain Dyson and Surgeon-Major Nariman have respectively delivered over and received charge of the office of the Deputy Sanitary Commissioner, Gujerat Registration District. Surgeon-Major W. K. Hatch to be Principal, Grant Medical College, Bombay, vice Brigade-Surgeon-Lieutenant-Colonel G. A. Maconachie, retired; Surgeon-Captain Herbert to be Professor of Ophthalmic Medicine and Surgery, and Professor of Comparative Anatomy and Zoology, Grant Medical College.

NAVAL MEDICAL SERVICE.

Fleet-Surgeon Richard Samuel Parnell Griffiths has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets, in Her Majesty's Fleet. Surgeon Frederick William Collingwood has been placed on the Retired List of his rank.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major John J. A. Raye resigns his commission. The under-mentioned officers having resigned their Volunteer appointments, cease to belong to the Army Medical Reserve of Officers:—Surgeon-Lieutenant H. W. Joyce and Surgeon-Lieutenant W. A. Wetwan.

MILITIA MEDICAL STAFF CORPS.

Surgeon-Lieutenant Luigi Walter Alfred Keiffenheim-Trubridge, M.D., from the 3rd Kent Volunteer Artillery, to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Royal Engineers: 2nd Cheshire (Railway): Surgeon-Lieutenant T. C. Bailey to be Surgeon-Captain.

THE REVOLT OF THE BORDER TRIBES.

Those medical officers who took part in the last Afghan campaigns, of whom there must be many in this country and abroad on foreign service, will follow the news with great interest from India regarding the rising of the tribes occupying the large extent of territory intervening between India and Afghanistan. The brilliant relief of the forts on the Samana Range by General Yeatman Biggs's force is most satisfactory. The most unsatisfactory item in the latest intelligence is, perhaps, that regarding the block or breakdown in the railway arrangements for the conveyance of the animal transport to the frontier. It is largely a repetition of the old difficulty, that which so hampered the movements of every branch of the service on the occasion of the last Afghan campaigns. It is needless to say that armies cannot move without transport, and in the mountainous belt of territory occupied by the independent tribes animal transport, being the only practicable one, is essentially necessary. The delay which will be caused by the block on the Indian railway of the North-West is a most unfortunate occurrence at the present moment, because an immediate advance is now of vital importance, with the view of striking a heavy blow against the opposing tribes and so preventing any further spread of the rebellion. Medical officers will recall the difficulties they experienced in "the rush" to the front, and those which afterwards followed in the movement of the field hospitals and hospital stores, and in the transport of the sick and wounded, on the occasion of the Afghan campaigns, although there was no such block on the railways as is reported to exist now. The unexpected is that which happens, and it is only fair to add that this great rising of the frontier tribes was a perfectly unexpected occurrence; still, it might have been imagined that the first thing to be done would have been the dispatch of officers to see that adequate railway arrangements, or the best that could be made under the circumstances, were made for the enormous increase of traffic to Peshawar and the North-West frontier. The difficulties to be overcome in the way of medical organisation and hospital administration for the different columns in the field will impose a great strain on the medical services. The military department of the Government of India have now had some weeks at their disposal in which to make their arrangements. They have a very large and splendid force at their command, and we can only confidently hope that the necessary transport will speedily be made available where it is so urgently wanted.

THE SOUDAN CAMPAIGN.

What with the widespread revolt of the border tribes on our Indian north-west frontier, South African affairs, the Soudan expedition, the Greco-Turkish war conference, and the condition of Crete, the Government has its hands full of difficult and anxious problems at the present time. Now that the Sirdar (Sir H. Kitchener) is on his way to the front we may soon expect to hear of some important movement of the Soudan expedition; meanwhile, Berber has been taken and occupied. The present position of affairs seems to be that garrisons have been established along the Nile at Dongola, Debbeh, Korti, Merawi, Abu Hamed, and Berber. There are five gunboats above Abu Hamed. A series of posts, held by friendlies, has been established extending across the Bayuda desert and completely covering the river. The whole of the tribes in the Desert are reported to be friendly. One hundred and sixty-five miles of railway have been completed. The Dervishes are in strong force at Metemmeh; those of them who retreated from Derber were attacked by General Hunter's gunboats and force, and fled into the Desert abandoning their stores. Osman D'gna is reported to be on the banks of the Atbara River. The Egyptian forces are in good health and spirits. The hospital and medical arrangements are working well, and arrangements generally are being completed during the present lull for any future movement that may take place. The Khalifa's forces at Khartoum are said to number 60,000 men. With the railway and Nile transport available Sir H. Kitchener can bring up his supplies for his force, but whether he will soon start for Metemmeh and then for Khartoum o not still remains to be seen.

MEDICAL EXAMINATION OF ARMY CANDIDATES.

A correspondent writing to the *Times* of Sept. 1st under the designation of "Suum Cuique" hits the mark in his remarks upon the late rejection of a successful candidate when he says that the War Office authorities have expressly warned parents and guardians that candidates for army commissions should be medically examined before commencing a special course of study for the competitive examination; and he inquires whether this was done in the case referred to. He adds that while, thanks to the present regulations, the physique of our young officers is excellent, the eyesight of too many of them is not so good as it ought to be. Candidates are now passed as fit with only one-sixth of normal vision. With such a degree of defective sight an officer might easily be placed under circumstances where he could not efficiently fulfil the military requirements of the occasion, and in night attacks, when the light is very little, a man with only one-sixth of normal vision would be practically blind. This is a matter which apparently requires to be looked into.

MEDICAL ARRANGEMENTS FOR THE FRONTIER.

The *Army and Navy Gazette* says: "The medical arrangements for the different brigades, divisions, and columns operating on the various lines of the frontier has necessitated much work and thought on the part of the Principal Medical Officer of Her Majesty's Forces in India, Surgeon-Major-General Gore. Some 23 British and native field hospitals have had to be mobilised in the proportion of about 7 British and 16 native hospitals. Further, 2 British and 2 native general hospitals have been established with field medical store depôts. The number of Army Medical Staff officers employed is approximated at 31, while some 65 Indian Medical Service officers have also been detailed."

THE SICKNESS IN BOMBAY.

As we have previously stated, the city of Bombay is still very unhealthy spite of the cessation of the plague. The prevailing epidemics of cholera, fever, and dysentery are, according to the *Times of India* of the 27th ult., continuing in evidence and in unabated severity. The death-rate is as high as 59·75 per 1000. The chief cause of the increase has been cholera, which has existed in Bombay in a more or less epidemic form for the last six weeks, but is now beginning to show a sensible decline. The fever mortality and that from dysentery continue to be high. The late plague and the results of famine, in addition to the presence of insanitary conditions, have no doubt lowered the health of the population and their power of resistance to disease-causes generally.

THE PLAGUE AT POONA.

The number of cases of plague in the special hospital is somewhat increasing. There were fifty-eight cases in hospital towards the end of last month, and some deaths from plague had occurred among the native troops in the Poona cantonment. In the Kirkee cantonment also several fresh cases of the disease had been admitted to hospital and many deaths had taken place.

Correspondence.

"Audi alteram partem."

THE ELECTION OF A DIRECT REPRESENTATIVE ON THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—Having been asked to allow myself to be nominated for the seat just vacated by Dr. Robert Rentoul as direct representative upon the General Medical Council, after careful consideration, I have decided not to do so on this occasion. The vacancy should, in my opinion, be filled by a northern representative, and should Dr. Samuel Woodcock, J.P., again come forward as a candidate I trust that all those members of the profession who accorded to me their votes at the last election will bestow them upon him at the present time. Dr. Woodcock is too well known by his works to require any introduction to the medical profession, and he would make an admirable representative; the fact that he is President of the Lancashire and Cheshire Branch of the British Medical Association should secure him the suffrages of at least the members of the Association and ensure his election. On another occasion arising, however, I shall, I hope, find myself in a position to accept the invitation to nomination should it be offered to me.

I am, Sirs, your obedient servant,

Hatfield, Sept. 15th, 1897. LOVELL DRAGE.

P.S.—Since writing the above I hear that Dr. Woodcock has refused nomination, but, at the same time, I understand that, as we have both refused, Mr. Victor Horsley has consented to come forward as a candidate. I believe that this consent of Mr. Horsley will be more than welcome to those who have the interests of reform in our profession at heart.

To the Editors of THE LANCET.

SIRS,—There can be little doubt, even in the minds of those who are as heartily in favour of the principle of Direct Representation as THE LANCET has shown itself to be, that recent occurrences have tended somewhat to discredit the principle as applied to the General Medical Council, and it therefore appears to be of the utmost importance that the profession, in choosing a successor to Dr. Rentoul, should assure itself as far as possible that there will be no likelihood of a repetition of the mistakes which have lately occurred, but that whoever may be chosen he should be one who is prepared to assist in carrying on the business of the Council as imposed upon it by the several Acts of Parliament under which it is constituted. One principal object, however, of having Direct Representatives on the Council at all appears to be that they may from time to time, as opportunity occurs, place before it in a temperate manner the views of their constituents on the various questions of professional interest which come before it—on such questions, for example, as the Midwives Bill, the increase of Direct Representatives, and the medical aid associations, to take but a few of the many important questions dealt with during the ten years that our representatives—Sir Walter Foster, Dr. Glover, and Mr. Wheelhouse—served us and the Council so well. The time is short before nomination closes to ascertain the opinions of any new candidates on these questions, and I would therefore suggest that if the Council of the British Medical Association could obtain the consent of Sir Walter Foster, whose actions on these subjects speak for themselves, to his nomination as a candidate, it would be very desirable that he should be sent back to the General Medical Council with the weight of practically the whole profession in England and Wales behind him.

I am, Sirs, yours faithfully,

Dulwich, Sept. 14th, 1897. H. NELSON HARDY.

"FORCIBLE REDUCTION OF POTT'S CURVATURE."

To the Editors of THE LANCET.

SIRS,—With reference to an annotation upon this subject in THE LANCET of Sept. 11th, it is to be hoped that those interested in the subject will observe the proportion of deaths recorded. Three deaths in thirteen cases, all within a week of the operation, is a large mortality, far exceeding that which occurs in treatment by careful fixation of the spine with general remedies. Forced extension without an anæsthetic carefully limited to the patient's powers of endurance is a far safer plan of treatment. It is one which I have been trying cautiously in a certain number of cases, and so far with good effects. For lateral curvature the forced reduction of the deformity promises, I think, excellent results. The patient should be placed upon a prone couch, the flat part of which should be long enough to support the whole length of the trunk. Then the surgeon standing over the patient is able to exert great power upon the projecting curves. It is of course necessary to keep up for a time, by mechanical means, the improvement made by manual force.

I am taking photographs of some cases treated in this manner in their different stages, so that I shall have some definite illustrations to prove the results of the treatment, notes of which I hope, with your permission, to publish in THE LANCET at some future date.

I am, Sirs, yours faithfully,

NOBLE SMITH.

Queen Anne-street, W., Sept. 13th, 1897.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Sept. 11th, at page 673, attention is drawn to the treatment of Pott's curvature by forcible reduction which has been recommended to the profession by Professor T. Jonnesco, of Bucharest. The annotation makes no mention of English writers in connexion with this treatment, which is described as "one of the most striking of the recent advances of surgery," although to them above all others is due the credit of the method; unfortunately, however, a long time has elapsed since the method was practised in England. The practice came to be abused, many patients dying under the forcible reduction. This abuse produced a pamphlet from Pott, which he dedicated to Dr. John Lewis Petit, one of the physicians to St. Bartholomew's Hospital. The brilliant successes attained by rest in spinal caries and the many fatalities by the old method in advanced cases stopped the practice. After Pott's death Sir James Earle put forward a plea for the resumption of forcible extension of the spine and pressure on the projecting knob in suitable cases; but he was as one crying in the wilderness. Pott's pathology of the disease had been approved by John Hunter, and succeeding generations swallowed both pathology, theory, and therapeutics without question until Lewis Sayre, of New York, re-introduced Earle's suspension head gear and a modernised form of his jacket. There were, however, in England surgeons at all times who possessed sufficient courage to think for themselves, and although Pott's great and just influence stayed the progress of spinal surgery it did not wholly arrest it, for we read in Abernethy's lectures on local diseases, for the publication of which we are indebted to the courage and enterprise of the Founder of THE LANCET, that in certain cases he recommended cutting down on the projecting spine. Abernethy thus describes the incident in his professional experience: "And it was proposed as a question, Could anything be done in this case? I said, 'I cannot tell you, except taking out the rings of the vertebræ.' But that was considered so hard an operation that it was not at all contemplated. ..... Yet such a thing has been done, and done in London, and at the very time this accident happened."

I am, Sirs, yours truly,

Dublin, Sept. 14th, 1897. GEORGE FOY.

THE LATE DR. BRAXTON HICKS.

To the Editors of THE LANCET.

SIRS,—A very important omission occurs in your notice of the late Dr. Braxton Hicks in the matter of his discovery of the rhythmical movements of the uterus in pregnancy. I am writing away from all books of reference, but I think I am correct in saying that he discovered and established the point completely in his own work. The discovery lay for years neglected till I pointed out that it is by far the most trustworthy of all the signs of pregnancy. Even now it does not receive the prominence from writers of text-books which its value deserves.

I am, Sirs, yours faithfully,

Llandudno, Sept. 11th, 1897. LAWSON TAIT.

INFANT INCUBATORS.

To the Editors of THE LANCET.

SIRS,—In the interests of the general public we desire to call your attention to the fact that the success of our Infant Incubator Institution at the Victorian Era Exhibition at Earl's Court has attracted the notice of unscrupulous imitators. We are informed, for example, that various persons are calling upon, and writing to, members of the medical profession, hospitals, infirmaries, &c., asking for their support, and falsely representing that they are opening branch institutions in connexion with us, and asking for the loan of children to experiment with.

We consider, under these circumstances, that it is our duty to warn members of the medical profession, also nurses, parents, and all public institutions, not to entrust their children to any applicants whatsoever without first taking every precaution to assure themselves that they will not be made the victims of showmen, as well as of inexperienced and irresponsible persons who seek to trade upon the established reputation of an invention that has been recognised by both the medical and the lay press.

The institution at Earl's Court is the first of its kind in England, and we have not made any arrangements, nor have we given anyone authority to further exhibit, at any exhibition or place of public resort in the United Kingdom, so that all persons, no matter what their credentials may seem to be, making application for space and intimating that they have the power to exhibit Mr. Paul Altmann's invention should be classed as impostors.

We are, Sirs, yours obediently,

SAMUEL SCHENKEIN,

Earl's-court, S.W., Sept. 8th, 1897. MARTIN CONEY.

"IS 'MEDICAL DEFENCE' DEROGATORY TO THE DIGNITY OF MEDICAL MEN?"

To the Editors of THE LANCET.

SIRS,—It is to be hoped that the thoughtful and temperate letter of "Registered Practitioner" in THE LANCET of Sept. 4th has attracted the attention of the profession. There is no doubt that our governing bodies, from the General Medical Council downwards, do consider that the defence of the practitioner is derogatory to their dignity. The reason for this is plainly owing to the composition of these bodies and to their non-representative character. If it could be brought home to the eminent men who direct the policy of our councils and corporations that by a more liberal course of action they could do much to ameliorate the lot of thousands of their less fortunate *confrères*, I feel sure that they would not consider such action derogatory. Your exhaustive series of articles on the "Battle of the Clubs" give an idea of the pecuniary loss which the profession is suffering all over the country owing to abuses which are perfectly remediable if our governing bodies were willing to take them in hand. It is to be hoped that those suffering from these abuses will lose no opportunity of pressing them on the attention of the powers that be until their extent is fully realised. Doubtless the promotion of the scientific progress of our profession is all important, but surely the protection of the material interest of those who practise it is at least equally so.

I remain, Sirs, yours faithfully,

Sept. 13th, 1897. W. G. D.

WE have received from the Volunteer Ambulance School the syllabus of courses of instruction of the classes for the training of stretcher bearers, to be held at the headquarters of the London Rifle Brigade, 130, Bunhill-row, E.C., commencing at 7.30 p.m., on Monday, Oct. 4th, 1897. Surgeon-Major H. F. Stokes, of the London Rifle Brigade, the Senior Medical Officer Instructor, appears to have taken every precaution to make the course a thorough one.

HOSPITAL ABUSE.

(BY OUR SPECIAL COMMISSIONER.)

XII.—BIRMINGHAM (*continued*).[1]

Origin of the Hospital Saturday Fund.—The Opposition to Weekly Subscription.—Workmen Pay Half the Expenses of the Hospitals.—Dangers of the Situation.—Dependence of the Hospitals on Working-class Financial Support.

THE Hospital Saturday Fund was established in 1874 on lines not only different from, but absolutely opposed to, those which are now followed. To-day its success depends on the careful organisation of a system of weekly contributions. The late Mr. Sampson Gamgee helped to convert the working men's fund for the extension of the Queen's Hospital into the Hospital Saturday movement. The first collection brought in £4705. After that there was a depression in trade; the collections were not so good, and sank in 1878 to £3134, which is the lowest figure on record. In 1882, after the tenth collection, which for the first time exceeded the inaugural collection, and amounted to £4888, Mr. Gamgee said: "The complete success of Hospital Saturday depends in no small measure upon the method of collecting the money, and this is a matter attended with no little difficulty. Acting on the experience gained with the working men's fund for the extension of the Queen's Hospital, our committee abstained most scrupulously from recommending any set method of collection. The recent incident which resulted in a workman recovering in a court of justice money said to have been stopped at a penny a week for Hospital Saturday is only recalled to point to a possible danger attending the system. The projectors of Hospital Saturday did not aspire to make it a success on the mere mechanical principle of 'many a little makes a muckle.' The penny-a-week system in factories and workshops is vastly older than Hospital Saturday, in instituting which it was hoped to sanctify a labour day by the sacrifices and loving thoughts of those yet blessed with strength to work on behalf of fellow-toilers laid low by injury or disease." Mr. Gamgee, so his fellow-committeemen said, in a public declaration on the subject, was "wedded to the idea of Hospital Saturday being a day of labour-sacrifice, and this was the foundation of the movement which he established. He strongly advised against our abandoning this as a method of collecting, and substituting for it the weekly method of contributing."

These quotations show that, if Mr. Gamgee did not foresee in full the complications that are now arising, he had in any case a very acute intuitive sense of the dangers ahead. If the object be to maintain hospitals on their present basis—that is, private initiative supported by voluntary contributions—then Mr. Gamgee's opposition to weekly collections was well founded. If, on the contrary, the object be to so reduce the contributions of the wealthy classes while so increasing the controlling influence of the working classes, as to render the demand for the municipalisation of the hospitals almost irresistable, then the present policy is right and the objections raised by Mr. Gamgee were wrong. In any case, the policy of collecting weekly contributions was ultimately adopted and has given the most brilliant financial results. This, of course, has not been attained merely by the line of policy followed. The success is due in a large measure to admirable organisation and to the energetic impulse given to the movement by the able and eloquent leadership of Mr. Smedley. This gentleman who is one of the leading accountants of Birmingham, unites to the wealth and exceptional business abilities which he possesses, a deep faith in the capacities of the working class. He further is able to impart to his speeches a humanitarian and democratic tone which goes to the heart of the working man. As a result, he has built up in a few years what seems to be one of the strongest and best organised working-class movements in the country. It is true that I do not believe he in the least understands the potentialities of the movement he has so skilfully organised; nor do I imagine Mr. Smedley fully appreciates the socialist conclusions which are the logical outcome of some of his speeches. Nevertheless, he has taught the working men of Birmingham socialist ethics, and this not in a theoretical, but in a most practical manner. Here are a few specimens of Mr. Smedley's eloquent teaching. I quote them from his speech delivered to the fourth annual *réunion* of old patients from the convalescent homes of Tynycoed and Marle, and delivered in the Birmingham town hall in November, 1895: "Still, our chief cause for pride lies in the convalescent homes which you [the workmen of Birmingham] have established." ..... "These homes are yours, as much yours as those to which you will return to-night. Not less yours because others share their advantages with you. It is only the selfish man—there are plenty of them living among us—who values what he has because others are without. There are men who derive pleasure from the thought that their possessions are greater than those of others. You value, I know, these homes in a far better manner because you rejoice that they are shared with you by others." Mr. Smedley then went on to show that, though these homes were managed exclusively by working men, they were well and economically managed, and this without vexatious rules and regulations, and further that they were conducted under the ruling principle that "if you want to be happy try to make those around you happy." "Make this the object of your lives," he exclaimed, "during the next twelve months, and I guarrantee it shall be the happiest you have ever spent. The only hope for the regeneration of the community rests with the working classes. I assure you of the well-to-do classes there are few who can spare time to bring about a great change. They are too much occupied with making and keeping their wealth, with the luxuries and pleasures they are able to obtain in spending it." ..... "If the objects of these societies (the Hospital Saturday Funds) are pressed forward with determination, there is no reason why the whole condition of the poorer classes should not be altered for the better and, in time, pauperism become practically extinct. We are under obligations to those amongst whom we live and move. Whether we recognise them or not we cannot get rid of them. I beg you, by the common interest we have in these homes, by the glimpses of happiness which we have obtained there—interest and happiness which have resulted from others recognising their obligations to you—to resolve that during the forthcoming year you will fulfil your obligations to others. I envy that man who, when the time has come for him to fall into that long last sleep which all must sleep—I envy that man who shall have the satisfaction of dozing off with pleasant recollections of the happiness he has been the means of bringing to others during his life. I care not what may be in store for you after that sleep; if your life has been spent in seeking happiness by giving happiness to others the dim and distant future can have no terrors for you, for you will carry with you the satisfaction of having brought that day nearer when misery and destitution shall be swept from our midst."

It is by steady, hard, plodding work, brightened and stimulated by such words as these, that, up to the date when they were pronounced, the working-class of Birmingham had raised for the medical charities of that town the princely sum of £156,459 10*s.* 6*d.* From 1873 to 1882 the collection fell a little under £5000 annually. In 1885 it exceeded £6000, it 1888 it amounted to £7689. In 1891 it was not far short of £11,000, and in 1895 it exceeded £13,000. For the last seven years the Hospital Saturday Fund, apart from maintaining its convalescent homes, its district nursing societies, and other institutions, has made a free annual gift to the medical institutions of Birmingham of £10,000. But it must not be forgotten that to obtain these enormous sums in pennies from the working classes it has been necessary to create an organisation by the side of which the trades unions, for instance, of Birmingham are feeble and impotent. Of course, Mr. Smedley will at once exclaim that his motives were of the purest, that pacific reform on humanitarian lines is his sole object; and I have not the slightest reason to doubt the truth of such an allegation. But Mr. Smedley will not always be there to guide and inspire the movements of the giant he has

[1] The previous articles on this subject were published in THE LANCET on the following dates: (1) Sept. 26th, 1896, Plymouth and Devonport; (2) Oct. 10th, 1896, Exeter; (2 *concluded*) Oct. 17th, 1896, Exeter; (3) Oct. 31st, 1896, St. Thomas's Hospital, London; (4) Nov. 14th, 1896, Liverpool; (4 *continued*) Nov. 21st, 1896, Liverpool; (4 *concluded*) Dec. 12th, 1896, Liverpool; (5) Jan. 2nd, 1897, Manchester; (5 *continued*) Jan. 9th, 1897, Manchester; (5 *concluded*) Jan. 23rd, 1897, Manchester; (6) Feb. 6th, 1897, Leeds; (6 *concluded*) Feb. 13th, 1897, Leeds; (7) April 17th, 1897, Coventry; (8) May 1st, 1897, The Royal London Ophthalmic Hospital; (9) May 8th, 1897, France, United Action and Legislative Action; (10) May 15th, 1897, Leicester; (11) June 5th, 1897, Nottingham; (12) July 31st, 1897, Birmingham; (12 *continued*) Aug. 14th, 1897, Birmingham; and (12 *continued*) Sept. 4th, 1897, Birmingham.

Digitized by Google

created. He has done what the trades unions have failed to accomplish. He has united as financial members of one organisation democratically governed, that is to say, capable of throwing Mr. Smedley himself out of office, 75 per cent. of the working-men of Birmingham, and it is Mr. Smedley who is my authority for this statement. Again, I repeat all this is based on the best of motives; but good intentions are said sometimes to lead to undesirable places.

The working classes of Birmingham, now united and organised as they have never been united before, and collecting among themselves an income of at least £15,000 a year, constitute a power that may some day be utilised for many other purposes besides that of building convalescent homes and subsidising hospitals. Indeed, it has already been resolved to limit the subsidising of hospitals. However large the amount collected by the Hospital Saturday Fund, it has been decided that not more than £10,000 shall be given as a free gift to the hospitals. Whatever is done with the rest will mean a new departure, a revolution, in the administration of medical charities. Indeed, is this not already the case with regard to the convalescent homes? Formerly such homes were built by wealthy and benevolent people and managed by them with the aid perhaps of some of the medical staff. Now they are the exclusive property of the working men, who themselves decide who shall, and who shall not, go there. Undoubtedly these homes, and Mr. Smedley in the speech quoted above emphasises the fact, afford the working men far more satisfaction than the hospitals to which they nevertheless contribute a much larger sum of their money. Thus, according to the last published account I was able to obtain from headquarters, the receipts of the Saturday Hospital Fund for 1895 amounted to a total of £13,497, and out of this, the convalescent homes cost £2250; the committee £150; the District Nursing Society, for services of nurses to Hospital Saturday subscribers, received £100; a balance of £997 was carried over; and £10,000 were given to the hospitals. Thus we find that already twenty-three and a half per cent. of the money spent for medical relief by the Hospital Saturday Fund is employed in accordance with the principles of a provident society. Further, in January, 1892, the Fund was incorporated under the Companies Act of 1862 as an association not for profit. Thus, I take it, the money could be spent as the committee think fit and therefore, if need be, wholly devoted to provident purposes. But if means of medical relief were organised independently of the hospitals in a satisfactory manner—and this has already been done in regard to the providing of trained nurses and the convalescent homes—the hospitals might lose a great deal more than the £10,000. The workmen not only subscribe to the Hospital Saturday Fund but they send subscriptions direct to the various hospitals so as to obtain the tickets they may require for their own use. Thus, for instance, taking an example haphazard, I find that the Birmingham Carriage and Wagon Co., contributed £75 1*s.* 5*d.* to the Hospital Saturday Fund; but they also sent £10 10*s.* direct to the General Hospital, and probably subscribed for tickets from other hospitals. Now, if the workmen were to organise their own medical relief all these sources of income might be withdrawn from the public charities. Though they are not in the least likely to do so, if judged by their present disposition, still it is necessary to reckon with distant, and, as yet, vague possibilities. We must think not only of the policy of an institution such as it is to-day, but also what it may become to-morrow.

With regard to the policy of to-day there are in reality two policies, the practical and the theoretical. The latter, like most theories is quite ideal. The workmen make a free gift every year of £10,000 to the medical charities. Great emphasis is laid on the word "free." They expect nothing in exchange; the £10,000 are bestowed in pure charity. Alderman Cook, chairman of the Hospital Saturday Fund, was interviewed by the *Birmingham Daily Gazette*, and our contemporary, on May 5th last, wrote: "The position of the subscriber to the fund in regard to the medical charities, was some time ago defined in the plainest language in the official organ of the movement, and Alderman Cook, in conversation with our representative, firmly supported the view in regard to this particular matter there set forth—'a subscription to the fund, whether it be weekly or yearly, gives no right whatever. If a man or woman presents himself or herself at a hospital and demands treatment as a right bought by a subscription to the Hospital Saturday Fund, he or she takes up an absolutely unjustifiable position. The subscription carries with it no right; the princely gift of so many thousands per annum carries with it no equivalent. It is a free gift to the free work of the medical charities of the town.'" In a word, the workman gave his pennies, like the rich man gives his pennies, simply and solely for the sake of aiding and succouring the suffering and the afflicted. This is very beautiful, but does it work out exactly on the lines in practice? Every medical man to whom I have spoken testifies, on the contrary, that workmen are constantly expressing their conviction that because they subscribe to the Hospital Saturday Fund therefore they have a right to be treated at the hospitals; and on this ground some have even claimed exemption from the payment of registration fees where these fees are imposed. Then again, now that the workmen are imbued with so high a sense of their social duties that they liberally subscribe to the hospitals, it was only natural to expect that the well-to-do classes, stimulated by this example, would largely increase the amount of their subscriptions. The very reverse is the case. While an immense majority of the working classes subscribe to the hospitals it is only a very small minority of the wealthy classes that contribute. Throughout the country there is a cry that, in face of workmen's subscriptions, the wealthy classes subscribe less. If this statement is not borne out literally by figures it is quite correct if we judge the figures proportionately to the wealth and numbers of the respective classes.

Mr. Smedley pointed out to me that, as a general axiom, we might take it that the subscription list of a hospital only lasts seven years, and therefore the number of new subscribers added to the list every year must be in the proportion of one-seventh to the total. But he complained that when the workmen began to subscribe, the committees of the hospitals became neglectful. Not only have the hospitals been negligent in respect to the wealthy classes, but they have been competing with the Hospital Saturday Fund by urging the workmen to subscribe directly to the hospitals instead of sending their money to the Hospital Saturday Fund, and offering to supply them with tickets as an inducement. On the other hand, one of the leading hospital surgeons complained to me that the Hospital Saturday Fund had reduced the direct subscriptions from the factories to the hospitals. They tried to get the money paid into the general Hospital Saturday Fund, under the promise that the managers of the Fund would see that the men got all the attention they required. The free gift of £10,000 was not altogether a free gift. The Hospital Saturday Fund issued letters of their own recommending patients, and no hospital could, under the circumstances, venture to slight such a recommendation. It was his opinion that the Hospital Saturday Fund fostered the idea that the hospitals were provident clubs. This the medical staff would never tolerate and he thought that, in the long run, the workman would withdraw their subscriptions and utilise them exclusively for their own purposes. As tending somewhat to confirm the opinions thus expressed, I may quote a passage from the organ of the Hospital Saturday Fund published in the issue of February 1895: "To a greater or less degree we believe every one of the Birmingham Medical Charities has recognised the provident principle. Bodies of workpeople—or in fact anyone—may subscribe a guinea to the General Hospital and receive six letters of recommendation. Once subscribers, they may purchase additional tickets at the rate of three shillings and sixpence each. A subscription of one guinea a year to the General Dispensary purchases eight tickets, and the minor ticket hospitals all sell the right of admission or treatment on similar terms. The working classes have been shrewd enough to avail themselves largely of the advantages thus afforded to them. The machinery of the Hospital Saturday weekly collection has afforded them facilities for the collection of their subscriptions by weekly instalments. The result is that nearly £6000 of direct subscriptions of the institutions is derived from this source annually, for which the fund gets no credit."

If to these £6000, direct subscriptions, be added the registration fees, and the £10,000 free gift, it is estimated that the working classes of Birmingham pay at least half the total annual cost, some £45,000, of the hospitals. Since 1873, when the Hospital Saturday Fund was first established, the wealth of the city is stated to have doubled, and it is absolutely certain that the subscriptions of the wealthy classes have shown no proportionate increase. In comparison they have, on the contrary, decreased, and it

Digitized by Google

is the subscriptions of the working men that have more than filled up the gap. But will the working men be content to continue to fill up the gap which the indifference of the wealthy creates. This is highly improbable. Why should the poorest sections of society show themselves more charitable than the wealthy? It may be said that hospitals are for the benefit of the working classes; but they exist, also, and equally, for the benefit of the wealthy classes. It is not only the duty of the rich to subscribe, but, in their own interests, they should do all they can to develop the highest possible skill among medical men. But for the hospitals this knowledge and skill would soon fall to such a low level that the wealthy classes would have to send abroad for surgeons and physicians, and this would cost far more than what they actually subscribe to the hospitals. The workmen are not going to provide with their pence schools of medicine for the benefit of the rich. Mr. Smedley, who as a middle-class man might take a more moderate view of the situation, wrote and circulated among the subscribers to the Hospital Saturday Fund the following threatening words, and this so far back as 1893:—

"Let us regard the position of the classes for whose sole benefit the hospitals are supposed to exist from one other point of view. Assume that they established a vast hospital and dispensary of their own and applied the sum of upwards of £20,000, which they now annually pay over to the charities, to its maintenance. Without much trouble they could increase this sum to £30,000 per annum, an amount nearly equal to the expenditure of the General, the Queen's, and the Dispensary. Assume that they had a stipendary medical staff, and refused the admission of students to their institution. The result would be disastrous to the present medical charities. No longer would the rising men in the medical profession compete for the honorary offices, for the experience which is to make their reputation, and consequently their fortunes, could no longer be obtained there. Hospitals without patients, or with only a few patients, would have no attractions for clever young medicos. The fact is that a large number of patients are essential to a successful hospital. The hospital managers and staffs cater for the multitude, so that their institutions may take high rank and their honorary officers and students may gain the widest experience possible."

This, of course, is but a threat. There is at present no proposal, no desire, to carry out such a scheme. But a big step in this direction is advocated. Again this is Mr. Smedley's suggestion. This gentleman, contrary to the opinion of the majority of the medical profession, does not recognise that there is any serious abuse of the hospitals in the sense of their being frequented by numerous patients who could well afford to pay private practitioners. On the other hand, and in harmony with the unanimous opinion of the profession, he does appreciate the very great abuse due to the overcrowding of the out-patient departments by trivial cases. He therefore proposes as a remedy the creation of provident dispensaries in connexion with the hospitals, and, where possible, on the same premises. These dispensaries should be open from 9 A.M. to 9 P.M., which would be an enormous boon to all patients. They should be in charge of well paid and thoroughly capable and experienced medical men. All recommendations, tickets, &c., to the hospitals, should admit, in the first instance, only to the dispensaries, and give a right to three weeks' treatment. The out-patient departments of the hospitals would be restricted solely to patients coming from the dispensaries for a second opinion. The dispensaries would serve as filters so that the hospitals would have to deal solely with cases where superior skill was necessary. These, I take it, would be treated on the basis of charity, whereas payment would be exacted for all, or nearly all, the dispensary patients. Each ticket to the dispensaries would represent a payment made either by the patient or those who gave him the ticket. For those who could not obtain tickets through the factories having a Hospital Saturday Fund the provident societies, mothers' meetings, &c., could get them from the permanent relief committees, which might give them gratuitously after due inquiry. This, I take it, would mean that all subscribers to the Hospital Saturday Fund would consider that they had paid, and paid to the full, for any medical treatment they might receive at the dispensaries, and would only become objects of charity if their case was so serious as to necessitate their transference from the dispensary to a hospital. But in this scheme I can find no indication as to what is to prevent the abuse of the dispensaries by the well-to-do. It seems to be forgotten that the trivial cases are not only an abuse because they crowd the out-patient departments, but, above all, they are an abuse because, being trivial cases, the patients could in most instances afford to consult a general practitioner. So far as the question of hospital abuse is concerned this scheme only attempts to meet a part of the difficulty. Nor does it give a satisfactory answer to the working men when they ask why they should subscribe so much to the hospitals while the wealthy classes subscribe so little.

Then there is the very important and threatening fact that the workmen's subscription is not a voluntary subscription. According to the letter of the law it is a voluntary subscription, but, as a matter of fact, the pressure exercised is so strong that it is well-nigh impossible to avoid making these payments. If it be true that seventy-five per cent. of the working and poorer classes contribute, they will never rest satisfied till they have by persuasive or coercive means compelled the remainder also to subscribe. Then if all the poorer classes pay, what argument can possibly be adduced for excepting the well-to-do classes from payment; yet at present, the majority of the wealthy classes do not give at all to the hospitals. As there is no machinery, such as that organised by the Hospital Saturday Fund, to coerce, by social pressure, persons in a good position and make them all subscribe, the workmen will surely, sooner or later, demand that a hospital tax be imposed by law. Thus it is that the Hospital Saturday Fund may ultimately prove to be the foundation of a movement that will lead to the municipalisation of the hospitals. It would be foolish to ignore so obvious a deduction. Of course it will be said that this is socialism, and so it is. But when Mr. Smedley, in the speech quoted above, taught each individual working-man that the convalescent homes were none the less his property because others shared them with him, and that only the selfish man valued what he had—namely, his private property—because others could not enjoy it, was he not teaching, both in practice and in theory, the doctrine of collectivism. What is there surprising, therefore, that such teaching and such organisation should lead to the socialistic solution of the problem—namely, the municipalisation or nationalisation of the hospitals? Under such circumstances, and considering the immense influence which Mr. Smedley exercises, and the fact that the hospitals are at the mercy of the Hospital Saturday Fund which he in a great measure governs, it seemed to me indispensable to describe the situation. This I have attempted to do historically and impartially. While expressing my opinion on some minor matters of fact, I have not sought or intended to express any views of my own on the fundamental principles at issue, nor have I attempted or desired to advocate any particular cause other than the necessity of forming a medical union, so that the members of the profession may be in a position to deal with these grave problems.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Faculty of Physicians and Surgeons, Glasgow.

THE following gentlemen, having passed the necessary examinations and having been elected by ballot, have been admitted to the Fellowship of the Faculty: George Henry Edington, M.D. Glasg; William Robert Jack, M.D., B.Sc. Glasg.; and Thomas Spence Meighan, M.D. Glasg.

Western Infirmary, Glasgow.

It is understood that Dr. Gavin P. Tennent, in consequence of the pressure of other professional duties, has requested the directors to relieve him of his responsibilities as one of the physicians to the infirmary. No official intimation of the vacancy has yet appeared, and unless rumour is strangely at fault there may possibly be such a rearrangement of the allotment of the wards as to obviate the necessity for the appointment of another physician.

Glasgow Corporation.

The sewage disposal committee of the Town Council have decided to give formal notice of the intention of the Council to promote a Bill in Parliament authorising them to deal with the sewage on the south side of the river. This is

Digitized by Google

another step towards the attainment of that long-desired end—the purification of the Clyde.

Dundee Infirmary.

The directors of the Dundee Infirmary have reduced the list of applicants for the position of medical superintendent to a short list of five, and a definite appointment may be shortly expected. The retiring superintendent, Dr. Nathan Raw, has been elected to a corresponding position in the Mill-road Infirmary, Liverpool. His work at Dundee has secured the warm recognition of the hospital authorities.

Sept. 15th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Beri-beri at the Richmond Asylum.

AT the last fortnightly meeting of the governors of the Richmond Lunatic Asylum the medical superintendent, Mr. Conolly Norman, stated that the beri-beri disease seemed to be declining in violence. His report, however, showed that since the last meeting of the board there had been five fresh cases, while two deaths had occurred, the disease having been complicated in one instance with dysentery and in the other with tuberculosis. The total number of patients attacked since June is 199—namely, 149 females and 44 males, with 4 nurses and 2 attendants. It is satisfactory to note that 172 of the former inmates of the Richmond Asylum have been removed to Portrane, and that it is hoped that 100 more may be accommodated there before the date of the next board meeting. Grangegorman female prison is, moreover, being altered and furnished for the reception of a further number of non-infected patients.

The Sanitation of Clontarf Township.

At the last meeting of the Clontarf Township Commissioners Lord Ardilaun, who occupied the chair, made some interesting observations in reference to the drainage and sanitation of that rising suburban district. The Dublin main drainage is now almost completed as regards the north banks of the River Liffey and the northern portion of the city. This is certain to improve the sanitary condition of Clontarf, the sewers from which now discharge into the northern main drain of Dublin. Lord Ardilaun stated that the Commissioners were at last in a position to borrow money with the object of further improving the drainage of their township and with a view to the ultimate reclamation of the slob lands at Fairview, which were of such injury not so much to the health as to the appearance of the district.

Lunacy in Ireland.

From the forty-sixth report of the Inspectors of Lunatics in Ireland, just issued, I find that although the population of this country is decreasing the number of lunatics is becoming greater, as on Jan. 1st there were 18,966 insane in Ireland, being an increase of 609 as compared with 1896. This increase has been steadily growing and is put down since 1880 at 5984. The average annual admissions for the years 1881 to 1890 amounted to 2792, and for the six years 1891 to 1896 to 3195. This increase in the number of admissions to public asylums has occurred throughout the country without distinction of district, in the prosperous city of Belfast equally with the impoverished localities, and is apparently still going on, for at the last meeting of the Londonderry Asylums Board, on Sept. 9th, the medical superintendent reported an increase of 25 inmates as compared with the same month last year, and he was granted an increase in the number of attendants. It surely demands some explanation. What is the cause of the increase of lunacy in Ireland?

Death of Mr. Hugh McHarry, L.R.C.P. & S. Edin.

I regret to announce the death of a well-known practitioner in Belfast, Mr. Hugh McHarry, which took place at his residence, Grosvenor Lodge, on Sept. 11th. Mr. McHarry had been for some time in failing health, but his end was hastened by an attack of influenza a few months ago. He had been in practice for about twenty-six years, and for a time was a dispensary medical officer. He was medical officer to the Royal Irish Constabulary at Anderstown. He was most popular with his patients.

The Royal Victoria Hospital, Belfast.

As previously announced in THE LANCET, the Belfast Corporation have signified their intention of granting six acres of the asylum grounds in Grosvenor-street, with an additional grant of four acres if all the patients are removed from the asylum, as a site for the Victoria Hospital. The ground, which will form an excellent site, is the exclusive property of the corporation, but in order to make the grant valid it is necessary to have the consent of the board of governors of the asylum. Accordingly, on Sept. 13th, at the usual monthly meeting of the Asylums Committee, a deputation from the supporters of the new Belfast Hospital appeared before them asking them to consent to the arrangement made by the City Council. After hearing the deputation a resolution was unanimously passed granting the request expressed by this deputation and furthering the object as far as possible. Previously to the motion being passed the Roman Catholic Bishop (a governor of the Asylums Board) said before he consented he would request the Corporation to provide a free site for the hospital (the Mater Infirmorum) which he was engaged building. He thought distributive justice demanded that the Belfast Council should treat their people (the Roman Catholics) in the same way as they had treated the Victoria Hospital. The chairman (Professor Cuming) said he thought there would be a great difficulty in giving a free site to the Mater Infirmorum Hospital, because it was obvious that it was in a great measure built, and could not be transferred to another site. Before the site can be acquired by the Victoria Hospital Committee it will be necessary to have a special Bill passed in Parliament authorising the City Corporation to grant the ground. This cannot be done before next session.

Sept. 15th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Etiology of Drinkers' Cirrhosis.

M. LANCEREAUX, who has made for himself a great reputation by his researches upon alcoholism, recently laid before the Academy of Medicine some important observations with regard to the true cause of the cirrhosis which affects drinkers. From a total of 210 personal observations he has come to the conclusion that in Paris the principal cause of cirrhosis is wine. That in general use is the red wine. Those addicted to the use of spirits (*l'alcool*) simply are rarely affected with cirrhosis; therefore alcohol cannot be assigned as the cause of cirrhosis in wine-drinkers. M. Lancereaux considers the potassium salts to be in fault, and has made certain experiments upon animals in this direction. He found that on administering potassium salts to animals they died after about from fifteen to eighteen months, and in a large proportion of them he found a cirrhosis "bi-veineuse." Another set of experiments proved that the abuse of alcohol brings on a fatty degeneration of the hepatic cells followed by a fatty cirrhosis. M. Lancereaux accordingly has come to the following conclusion—that wine, and especially plastered wine, is the cause of atrophic cirrhosis, and it would therefore be as well to prohibit the plastering and sulphating of wines.

Intestinal Lavage in Digestive Intoxications.

At the same meeting of the Academy of Medicine M. Clozier, of Beauvais, read a number of observations showing the efficacy of intestinal lavage with a quantity of fluid which is allowed to escape immediately afterwards. The fluid employed is water which has been boiled, used pure or somewhat saline, or containing salol. The injection must reach as high as possible so as to affect the more microbes. By this method the intestinal intoxication is weakened from day to day, the temperature becomes regular, and the general condition improves. M. Clozier has observed various typhoid conditions improve greatly under this treatment, and even eclampsia undergoes a favourable modification under the influence of lavage by simple boiled water.

Incontinence of Urine in Relation to Infantile Hysteria.

At the recent Congress of Neurologists M. Cullere, of Roche sur Yon, presented the following thesis: that urinary incontinence is a sign of a disturbed mental balance. In his eyes it is a manifestation of hysteria, and always develops in a soil duly prepared by heredity. Among the parents of children who suffer from incontinence

Digitized by Google

are found diverse manifestations of hysteria, incontinence itself, alcoholism, various forms of neuropathy, and, to a less degree, sundry psychoses. Infantile or young hysterics are frequently descended from parents of unstable mental equilibrium or those who are degenerate, and those affected with urinary incontinence are notably like the hysterical in their mental instability and their extreme "suggestibility." Among occasional causes of incontinence M. Cullere reckons, as in hysteria, vivid emotional disturbances, traumatism, and infectious diseases, especially measles. Finally, the diagnosis of hysteria in incontinent children is justified by the existence in a number of cases of other symptoms of this neurosis.

Pathogenic Microbes in Vegetables and Market Garden Produce.

M. Brandeis, of Bayonne, has just called the attention of hygienists to the dangers which accrue to public health from the practice of using human manure for watering market garden produce which is so frequently eaten raw. M. G. Roux has laid before the Society of Medicine of Lyons a communication on the same subject, wherein he draws attention to the resisting powers of certain microbes deposited on vegetables and the extreme difficulty of removing them by repeated washings. M. Guiraud, of Toulouse, has also recounted his experiences as to the produce of the market gardens around Toulouse, where human manure is used. An outbreak of typhoid fever occurred some months ago at Toulouse, and M. Guiraud set himself to search for the bacillus of Eberth and the bacterium coli commune, but, less fortunate than M. Brandeis, M. Guiraud has not been able to isolate the bacillus typhosus. He frequently found "para typhoid bacilli"—i.e., bacilli closely resembling that of typhoid fever, which cause lactose to ferment feebly and redden litmus only after many days; others would not coagulate milk and grew very sparingly upon potato; but he never came across colonies presenting the undeniable characters of Eberth's bacillus. On the other hand, in sixteen samples gathered haphazard, such as materials for salads, strawberries, and the like, in nine he was able to establish the presence of large quantities of the bacterium coli with all its characteristic reactions. With three of these cultivations M. Guiraud made intra-peritoneal injections of 2 c.c. respectively into three guinea-pigs. All were very ill, and one died forty-eight hours after the injection. A post-mortem examination showed a sero-fibrinous exudation on the peritoneum, obvious peritonitis, and acute congestion of the intestines, the lungs, and the kidneys.

Army Medical Reserve.

An important decree has been issued relative to the medical officers of the reserve and of the territorial army. Medical officers of the reserve must be either retired military surgeons who seek appointments in the reserve, or civilian medical men who have graduated as M.D. at a French faculty, and who are available for duty with the army on active service. Retired military and naval surgeons may be appointed to the reserve with the rank which they held when on active service. Civilian medical men can on their first joining the reserve only hold the rank of assistant-surgeon-major (*médecin aide-major*) of the second-class. Their fitness for this position is ascertained by a special examination the subjects of which are prescribed by a Ministerial regulation; they are admitted to this examination as students when they have completed the class attendance required by the Minister of War. The regulations with respect to promotion are as follows: Civilian medical men appointed to the reserve cannot in time of peace rise to a higher rank than surgeon-major (*médecin-major*) of the second-class, and that only after having passed a special examination the subjects of which are sanctioned by the Minister of War and are such as to test the officer's knowledge of administrative work and of the military aspect of his duties. Ex-military surgeons can rise by promotion in the reserve to the rank of surgeon-major of the first-class. The minimum period of service necessary for rising from any rank to the step immediately above it is fixed at four years in the case of assistant-surgeon-majors of the second-class, and at six years in the case of assistant surgeon-majors of the first-class or surgeon-majors of the second-class. At the same time, the length of service required for promotion to the rank of assistant surgeon-major of the first-class is reduced to two years in the case of officers of the reserve who are filling, or who have filled, the position of professor or assistant professor in the faculties of medicine; of hospital physician, surgeon, or obstetric physician in the cities where these appointments are awarded by competition; of *chef de clinique* or prosector appointed by competition in the faculties or schools of medicine; or of resident medical officer of a hospital appointed by competition in cities which possess a faculty of medicine or a combined faculty of medicine and pharmacy.

Sept. 14th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Marcello Malpighi.

ENGLAND should certainly have been represented at the unveiling of the monument to the great Italian physician and biologist on Wednesday, Sept. 8th, for it was from England that he won recognition and honour when in his native Italy he had to go into hiding to escape imprisonment or worse. If, however, she had no representative on the occasion, amends were made to her for the omission by nearly every orator who spoke—by none more than by Professor Todaro, who holds the Chair of Anatomy in our medical school, and whose brilliant discourse was almost as much an eulogium of the Royal Society of London as of the mighty nature-student it sought to commemorate. But I am anticipating. For many years a movement has been on foot to erect to Marcello Malpighi a monument at his native Crevalcore, the little Emilian town which but for him would only be remembered as the scene of the encounter between Marc Antony and the Consul Pansa. On Wednesday, the 8th inst., that movement issued in a conspicuous success, the monument itself being a *chef d'œuvre* of the sculptor, Enrico Barberi, and the ceremony of its unveiling having attracted as distinguished an assemblage of Italian "leaders and luminaries" in medicine and biology as the kingdom is at this season capable of mustering. The day was all that could be desired, and as the veil fell from the grand impressive figure—represented sitting, book in hand, in profound meditation—the glorious sunshine seemed to exult in lighting up the features of the "sworn enemy of obscurantism," and in reminding the spectators of the darkness through which that figure had led the way towards "the ampler ether, the diviner air" in which modern science lives and moves. Born of farmer parents on March 10th, 1628, young Malpighi, early left an orphan, matriculated at Bologna, and soon distinguished himself in literature, philosophy, and finally in the medical school. The controversy between the moribund Aristotelianism and the Galilean induction had not yet resulted in the decisive defeat of the former, which had still strength enough to make its sting felt by young aspirants like Malpighi to university preferment. In fact, after graduating in 1653, he had to flee from his Alma Mater and take refuge at Pisa in the Chair of the Theory of Medicine created for him by the Tuscan Grand Duke Ferdinand II., where, once left with a free hand to experiment and a free voice to teach, he made his influence felt for good far beyond the limits of his subject and the precincts of his school. From 1656 to 1659 he fought the battle of inductive research, converting his colleagues from "Galenism" and maturing those studies which were afterwards to fructify in nearly every walk of medicine. So assiduous and laborious was his life that, combined with the local malaria, it impaired his strength for a season, and he had to return as a private individual to his Bolognese Alma Mater. He had by this time, however, shown what he was capable of, and after, when, in 1660, making the first application of the microscope to anatomy, he became, as Virchow has shown him to be, the founder of modern histology and the virtual anticipator of Schleiden and Schwann in referring the fundamental tissue of every living organism to the parent "cellula." Not only so, but (in Virchow's own words) "by discovering the capillary current through which the blood passes from the arteries to the veins he succeeded in filling up the chasm (no small one) left in the physiology of Harvey, his illustrious predecessor, and in convincing the world of science that the 'circulation of the blood' was an irrefragable fact. He thereby laid the secure lines on which his successors have reared the edifice of modern physiology and pathology; nay, more, his acute intellect penetrated so far as to discover the elements on which rests the theory of the composition of the blood." This testimony of the great Berlin pathologist was supplemented, at the ceremony of Wednesday

Digitized by Google

last, by that of Kölliker, of Wurzburg, who called him "the founder of embryology"; while Haeckel was also quoted to the effect that "in Malpighi we can trace the predecessor of Darwin in the theory of natural selection." Work the significance of which it has taken two centuries to appraise had even then brought him recognition in his native Italy, and we find him in 1662 Professor of Anatomy and Medicine in the University of Messina. But the Sicilian seat of learning was too obscurantist for so professed a votary of Hippocrates and nature study, and his life there was clouded and saddened by priestly and even academic persecution, denouncing him for his vivisection and his post-mortem examinations, and finally assuming so menacing an attitude that he had (as already stated) to go into hiding at Corticella. Still, even in enforced concealment he worshipped Nature, as the early Christians worshipped God in the Catacombs, and to this period we owe his researches on nearly every organ in the human frame, to say nothing of "comparative" work in the anatomy of the eagle, of the sword-fish, of the thunny, of the torpedo, of the glow-worm, and of intestinal worms in man and brute alike. In 1666 came forth his classic work, "De Viscerum Structurâ," whereupon the Royal Society of London begged him to give it a compendium of his findings. He sent it by way of answer his magnificent "Epistola de Glandulis Conglobatis." From this date more than friendly relations subsisted between him and the great English association. It placed his bust side by side with that of Newton in its great hall, and at its instance he was induced to publish his masterpiece, "De Bombyce" (on the silkworm). Of this treatise it will suffice to say that two centuries have only enhanced the admiration that hailed its first appearance, and that not only experts in the subject such as Reaumier, Cornalia, and Maillot accept it still as a classic, but that in 1878, during the French International Exposition in Paris, when the International Congress held its sittings, the Government of the Republic reprinted the treatise at its own expense and presented a copy to each member of the congress then present. Once more from London came the earliest and most cordial appreciation of his work "De Anatome Plantarum" which so fascinated Cuvier more than a century later for its demonstration of the respiratory function in vegetable organisms. English attestation of his signal merits had now a contagious effect on his compatriots and we find the enlightened Pope Innocent XII. rebuking the superstition of his order and appointing Malpighi his body-physician and "archiatro" (chief consultant) at the Pontifical Court. Here the much-tried nature student found rest at last, pursuing his researches under every facility papal munificence could provide and rectifying the frontiers of science in every direction till, after four years' tranquil activity, he succumbed to a stroke of apoplexy in 1694. His own pupil, whom Italians delight to rank with Sydenham as the "Hippocrates of Italy" — that great practitioner being honoured as the "Hippocrates of England"—tended him to the last, and by special request made a post-mortem examination of his body—a service quite in keeping with the spirit of the master whose researches on malaria prompted him to those further investigations so honourable to Baglivi. So lived, so died Marcello Malpighi, and if he has had to wait for due recognition, even for a monument in his native town, till the close of the nineteenth century, that only attests his genius and its triumphs the more, as proving how far he outsoared his contemporaries, and how truly it was said of him on Wednesday last that "being dead he yet speaketh." As to the ceremony solemnised on that day I have no space to dwell on its merely picturesque or purely rhetorical incidents. Be it enough to say that sculptor, speakers, and audience were all worthy of the occasion, and that with due official honour Italy received another accession to her "silent population of marble"—"silent," yes, but whose presence is eloquent of her mighty past and fraught with lessons she will do well to re-learn.

Sept. 11th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Insanity in Prisons due to Idleness.

THE labour unions have so influenced legislation that the industries hitherto carried on in the prisons have been greatly curtailed. The result has proved most disastrous to the health of the inmates. Insanity is the predominant disease, and so frequent has that become in some prisons that the prisoners have been set to work at tasks devised for the purpose, and with marked relief. In New York the prisoners have been allowed to make articles for use in the charitable institutions of the State, but no prison-manufactured article can be sold in the markets. This policy has diminished the former prison industries, but there is still enough to do to partially employ the prisoners.

Medical Inspection of Public Schools.

I have noticed the inauguration of medical inspection of the children of the schools by the Board of Health. The quarterly report of the work done has been published which shows the different kinds of diseases which may affect children who are mingling with healthy children. Parasitic diseases lead in the list, being 2627 in number. Of contagious diseases of the eye there were over 700 cases; of skin diseases there were 175; of diphtheria, 91; of measles, 51; of scarlet fever, 20; of mumps, 117; of chicken-pox, 93. Though the propriety of the inspections were at first regarded as very doubtful, yet the results prove its great importance. In Chicago a similar inspection has been in progress for a year with the following results: 744 reports of individual cases led to the discovery of 2617 cases in their homes; 231 cases of scarlet fever discovered 745 cases at home; 46 school cases of measles revealed the epidemic prevalence of this disease in several parts of the city. In October impetigo contagiosa became prevalent in seven schools, but was arrested after excluding 107 cases and employing suitable preventive measures.

The Treatment of Sunstroke.

Sunstroke is the most prominent disease of this city during the season of extreme heat. The mortality has generally been excessive. A recent study has been made of the 805 cases treated in the various hospitals in 1896, which gives some interesting results. The ten days, Aug. 4th to Aug. 14th, include the period of the greatest intensity of the conditions causing sunstroke. There was excessive and prolonged high temperature with high humidity. Clinically the cases were divided as follows: (1) heat prostration; (2) the asphyxial form; and (3) the hyperpyrexial form. There were 247 of the first class; the temperature did not exceed 105° F.; all recovered. Of the second form there were 38 cases; they lost consciousness, but the temperature did not exceed 105°; all recovered. Of the third form there were 520 cases with 132 deaths; each one had a temperature of 105° or upward, and but few retained consciousness. The difference between the three classes was one of degree and not of kind. The majority of sunstrokes occurred between 2 and 5 P.M., and between 7 and 10 P.M. The fatal complications were meningitis, pneumonia, and exacerbation of chronic kidney disease. The cause of death in most cases was failure of the respiratory and cardiac centres. In fifteen cases the changes in the nervous system were examined microscopically. All showed more or less changes in the chromophilic plaques of the ganglion cells. These plaques in some cells were changed in shape and were fewer in number; in some they appeared to be broken up or to have entirely disappeared. In three cases referred to there was universal exhibition of acute parenchymatous degeneration of the neurons of the whole neural axis. In the brain cortex and in the cerebellum the cells showed the same stages of degeneration. The spinal-cord cells were apparently not so extensively involved. These facts prove that there is a toxic cytolysis in isolation, or cell resolution of the neurons, which depended upon the condition of the body forces, the eliminative capacity of the body, and the duration of the poison. The treatment of the first class of cases was the same in the different hospitals—namely, rest in bed, cool sponge bath, an ice cap, and phenacetine for the headache. In the second class, or asphyxial cases, tub baths were given at 60° F., or sponge baths, or if coma and nervous symptoms required it the patients were put for a few minutes into the ice bath. In the third, or hyperpyrexial cases, hydrotherapy was employed in some form in all cases. It differed in application and in the temperature of the water. The records of mortality in the different hospitals furnish a fair estimate of the efficacy of the methods employed. The mortality among the patients treated with ice baths, and the bath continued until the temperature had fallen to about 103° or 102° F., varied in the different hospitals from 18 to 27·5 per cent. When in some cases the ice pack was used instead of the ice bath the mortality was 25·5 per cent. When the ice

Digitized by Google

bath was given for ten minutes, irrespectively of the point to which the temperature fell so long as it remained above a safe limit, the mortality was 40 per cent. Among patients treated with the bath at from 50° to 75° F. the mortality was one-third. When the baths were given at 90° to 110° F., and reduced in about fifteen or twenty minutes to 72° F., the results did not seem so favourable as with the cold baths. Among the patients treated with a needle spray from a hose attached to the cold water faucet the mortality was 11·5 per cent. Cold packs followed by hot packs in 197 pyrexial cases gave a death-rate of only 5 per cent., or, counting 8 patients who died a week later, the mortality was but 9·13 per cent. The death-rate of sunstroke, as given in Quain's Dictionary of Medicine, is from 41 to 50 per cent. In the entire number of cases of hyperpyrexia as recorded in the paper under consideration (540) the death-rate was 25·38 per cent. Therefore the treatment employed in the various city hospitals has given very satisfactory results. Briefly, the best treatment seemed to be a needle spray, or ice bath, or cold pack, till the temperature fell to 103° or 104° F., followed immediately by a hot pack, with stimulants and sedatives as the physician's judgment might deem necessary.

Aug. 19th.

Obituary.

JAMES MUTER TURNBULL, M.D. EDIN., F.R.C.P. LOND.

DR. TURNBULL graduated in 1839 and went to Liverpool shortly afterwards, when the town was extending rapidly north, south, and east, while the population was increasing enormously. He was elected physician to the Northern Hospital shortly after its erection, and to the Royal Infirmary some years later. He was also physician to H.M. Customs, to the Queen's, the Scottish Widows', and other life assurance societies. He had for many years a considerable consulting practice, being shrewd, observant, and very painstaking, having beneath a somewhat caustic manner a really kind heart. In 1876 he was elected President of the Liverpool Medical Institution, and on resigning his office as physician to the Royal Infirmary he was elected honorary consulting physician, which office he held at the time of his death. Dr. Turnbull retired from practice fifteen years ago, being a martyr to chronic rheumatism. He went to reside in Tunbridge Wells, where he died at the Spa on the 7th inst. in his eightieth year. In 1870 he married Miss Maxwell, daughter of a late well-known and highly respected Liverpool merchant. His funeral took place on the 9th inst. at Rusthall Churchyard, Tunbridge Wells.

A PROJECTED PUBLIC HOT WATER SUPPLY.—An interesting demonstration was held at the Crystal Palace last Wednesday of a new and ingenious process of obtaining hot water. The apparatus is so designed as to place within the reach of everybody a gallon of hot water for one halfpenny. The source of heat is the ordinary street gas lamp. Over the flame, at a distance to prevent interference with complete combustion, is placed a coil in which steam is generated. By its own tension this steam is driven under some pressure to the foot of the lamp in which is contained a reservoir of water connected with the main in the ordinary way. By a mechanical contrivance so familiar to everybody now, the hot water may be drawn off by placing a halfpenny in a slot. There is little doubt, we think, of a great future for this invention, as it obviously presents an important bearing upon domestic, dietetic, and hygienic questions. It is a curious fact that no one has hitherto thought of utilising the enormous quantity of heat that is dissipated from the street gas lamps. Some estimate of this quantity may be derived from the fact that over a quarter of a million sterling annually is spent upon street lighting. The light, however, is utilised, but the heat in the majority of cases is wasted. This novel enterprise is being undertaken by the "Pluto Hot Water Syndicate, Limited," 52, Queen Victoria-street, E.C. The departure has so many interesting features in relation to domestic economy and comfort, chiefly in connexion with its application to the rapid and economical preparation of hot food and beverages, as of beef-tea or cocoa, that we propose to return to the subject at greater length in a future number.

THE BRITISH MEDICAL ASSOCIATION.

MEETING AT MONTREAL.

THE sixty-fifth annual meeting of the British Medical Association was opened at Montreal on Tuesday, August 31st, under the presidency of Dr. T. G. Roddick, Professor of Surgery in McGill University.

The occasion was an interesting one, as this was the first time that a meeting of the Association had ever been held outside the British Islands. The choice of Montreal for the departure was considered on all sides to be a very happy one. As the chief city in the senior colony of the Empire Montreal had paramount claims upon the consideration of the British Medical Association, while the beautiful and beautifully situated city has always been famous for its kindness and hospitality to visitors. Montreal also possesses spacious public buildings and all other facilities for the accommodation of a large crowd, while the noble hospitals well repay the thorough investigation that a medical congress was sure to bestow upon them.

The dinner given by Dr. Roddick at St. James's Club on Monday evening to the officers of the Association and a large number of guests formed a pleasant prelude to the hospitalities of the week. Amongst the company were the Earl of Aberdeen, the Governor-General of Canada, Sir Adolphe Chapleau, the Lieutenant-Governor of the Province of Quebec, Lord Strathcona and Mount Royal (to give the sonorous title under which Sir Donald Smith, the eminent colonial politician, is now concealed), Sir William Hingston, Sir William Van Horne, and the Mayor of Montreal, Mr. Wilson Smith. The proceedings were of a thoroughly enthusiastic order; in particular, the toast of the health of Lord Strathcona met with a great reception; for Montreal, mindful of Sir Donald Smith's munificence to the city, has warmly welcomed his elevation to the British House of Lords.

The programme of the proceedings was definitely commenced on August 31st at noon, when the Bishop of Niagara gave an address at the opening service, which was held in the English cathedral. The Bishop of Niagara is better known to Canadians as Dr. Dumoulin, and occupied the pulpit at St. James's Cathedral, Toronto, for many years, where he earned for himself the reputation of being one of the most eloquent preachers in the Dominion, a reputation which those who heard him on this occasion can well understand to have been merited.

On Tuesday afternoon the first or adjourned general meeting was held, at which Dr. Roddick delivered his presidential address to a large and appreciative audience.

On the evening of the same day the Earl of Aberdeen held a reception at Laval University, when the guests had the privilege of hearing an address by Professor Charles Richet, the official delegate of the French Government, and Professor of Physiology in the University of Paris. The subject of Professor Richet's address was the Work of Pasteur and the Modern Conception of Medicine, and his address was designed to show that the union of medicine and science is indisputable, although absolute scientific methods may be out of place by the bedside, and can at any rate never take the place of observation, sympathy, and tact. "If I were ill," concluded Professor Richet, "I would not seek the aid of a chemist or of a physiologist, and medicine is not to be learned from the books of Claude Bernard or of

Digitized by Google

Pasteur. Clinical instruction is necessary, such as long observation of patients alone can furnish. Prophylaxis diagnosis, prognosis, therapeutics, are not to be learned in scientific books. Something else is necessary—observation, long, patient observation, the old Hippocratic observation, without which there can be no good physician. Young students must be guided in the examination of patients by experienced practitioners, and no one, I presume, would be guilty of the folly of proposing to replace the clinical ward by the laboratory. But without laboratories the clinical department must remain incapable of scientific advance, and this condition of stasis is assuredly undesirable. For in spite of all the progress which has been made, much yet remains to be done. Are not tuberculosis and cancer, for example, the disgrace of medicine? I appeal to all medical men here present. Is there any one of you, gentlemen, who in the presence of such painful modes of death does not feel himself humiliated to the bottom of his soul by his powerlessness?"

On Tuesday evening, also, at the Windsor Hotel, a banquet was given to Lord Lister by the members of the Montreal Medico-Chirurgical Society, the President of the society, Dr. George Williams, occupying the chair. After dinner an address was presented to Lord Lister congratulating him "on having been selected by the best Sovereign that ever graced a throne for the high distinction of a peerage." The address concluded with the following testimony to the estimate in which Lord Lister is held in Canada: "In advancing scientific and practical surgery you have advanced every branch of the healing art, and by investigations which have led you to the detection of the causes of disease you have brought us to a knowledge of the hindrances to the healing process. Henceforth present and future generations may point to your lordship with pride as the man who brought relief from suffering into every quarter of the globe. May your years be many, and may they be filled to repletion with the happiness which is born of having done nobly and well."

On Wednesday morning the work began in the various sections by the delivery of the addresses of the presidents of the sections. In the afternoon the second general meeting was held, after which the interesting function was witnessed of the presentation of the honorary LL.D. degree of McGill University to ten distinguished members of the Association and to one delegate. The delegate was Professor Richet, concerning whom the Dean of the Medical Faculty, Dr. Craik, made the following amiable little speech in presenting him to the Chancellor of the University, Lord Strathcona:—

"M. Charles Richet, Professor of Physiology in the University of Paris, official delegate to this meeting from the Government of the French Republic and from the University of Paris; a man who has made his mark in very many domains; as the pure physiologist in connexion with the working of the heart and of the nervous system; as a pathologist and bacteriologist by his studies along with Hericourt into the subject of serum therapeutics, in which line he was the first to make those studies which nowadays are so widely known in connexion with the treatment of diphtheria and other diseases; in scientific journalism as the editor of one of the greatest French scientific journals, and as a student of psychology, in which, with Crookes, Sidgwick, and other eminent scientists, he has soared into transcendental realms."

Dr. Henry O. Marcy, whose interesting paper on the Advantages of the Absorbable Suture was read to the Surgical Section of the Congress, enjoys the memorable distinction of being Lord Lister's first American pupil, and on his return to America in 1870 he established a laboratory for the study of wound infection, and opened a hospital in order to demonstrate the practical value of antiseptic surgery. In the field of antiseptic surgery in America he was the pioneer, subjected at first to much criticism, but long since recognised as an authority. Surgery is indebted to him, not only for the introduction of buried animal sutures, but for quite a number of special operations, notably the radical cure of hernia in the male by the restoration of the obliquity of the inguinal canal, first rendered possible by the use of buried animal sutures, and published by him in 1871. He opened the discussion upon antiseptic surgery at the International Medical Congress held in London in 1881. Dr. Marcy's paper will be found reported in the proceedings of the Surgical Section.

On Wednesday afternoon a garden-party was held in the grounds of the Royal Victoria Hospital, a noble edifice erected and presented to the city by the two Canadian peers, Lord Mount-Stephen and Lord Strathcona. On the evening of the same day Lord Strathcona held an at home in his splendid house in Dorchester-street, the rooms of which were crowded. The guests were received by Mrs. Howard, in the absence of Lady Strathcona.

On Thursday afternoon Lord Lister laid the foundation-stone of the Jubilee Nurses' Home in connexion with the Montreal General Hospital in the presence of a large assembly. On the same afternoon a large party of the Association were entertained at a luncheon upon "The Mountain" by the Lord Mayor and Aldermen of Montreal. The day was all that could be desired, a fresh breeze tempering the heat of the sun, and the clearness of the atmosphere permitting the visitors to have the full benefit of the famous view.

Among the numerous pleasant hospitalities of the week must be mentioned an afternoon tea and reception at the Art Gallery given by Miss Roddick; garden parties given by Mrs. George Hague, Mrs. J. Ross, and Mrs. S. Greenshields; and a five o'clock tea at which Mrs. S. Finley was the hostess. On Thursday a golf match was played on the links of the Royal Montreal Golf Club at Dixie between Canadian and English medical men, and on Friday a special exhibition game of lacrosse was arranged, the contestants being the Montreal Lacrosse Club, which has many times held the championship of the Dominion, and a team from the Indians of St. Regis. The Royal Montreal Golf Club and the McGill University Cricket and Lawn Tennis Clubs all kindly extended to the members and guests of the Association the privileges of full membership.

The trade exhibits in the Annual Museum were well housed at the Victoria Skating Rink, and if there were not as many representatives of English firms as could have been desired, yet this in a measure was compensated for by the presence of many firms whose wares are not usually seen in this annually recurring exhibition.

A feature of the meeting which was much appreciated by the members was the issue by the Association of a daily journal giving reports of the proceedings of the general meetings and sections. With considerable enterprise the editorial staff of the daily journal published, not only a programme of future events and a *précis* of past ones, but the full text of the various addresses and summaries of the debates which ensued.

The official proceedings of the Congress were brought to a close at the fourth general meeting, which was held on Friday afternoon, when Dr. Hermann M. Biggs, the eminent bacteriologist to the New York City Health Department, delivered the Address in Public Medicine. A long abstract of this address, which was listened to with keen interest, will be found in our report of the meeting. The social proceedings terminated on the evening of the same day with a conversazione held in the grounds of McGill University.

The Montreal meeting of the British Medical Association will be remembered by those who took part in it as one of

Digitized by Google

the most brilliantly successful of the annual gatherings of the Association. The fact that this is the first occasion during its sixty-five years of existence that a meeting has been held outside the limits of the United Kingdom marks its exceptional character, and the lavish hospitality bestowed upon the British members and American guests by the warm-hearted Canadians will long be remembered.

THE GENERAL MEETINGS.

THE FIRST (ADJOURNED) GENERAL MEETING.

The first general meeting of the Association was held, or rather completed, in the Windsor Hall, Dominion-square, Montreal, on Tuesday, Aug. 31st, at 2.30 P.M., having been adjourned from London, where, it may be remembered, the first part of the meeting took place on Tuesday, July 27th, at Exeter Hall. Among those present on the platform were the Earl of Aberdeen, Lord Lister, and Lord Strathcona.

The chair was in the first instance taken by Dr. ROBERT SAUNDBY, President of the Council of the Association, who had occupied that position at Exeter Hall in the absence of Dr. Roddick, the new President. Dr. Saundby having retired, Dr. Roddick took the chair, and began by introducing to the meeting the Mayor of Montreal, who welcomed the members to the city in an eloquent speech the purport of which was to show that it was right and fitting that the first meeting of the British Medical Association ever held outside the British Isles should be held in the metropolitan city of the Dominion of Canada. His honour concluded by begging "the guests of Montreal, after visiting the country, to tell it abroad that Canada had a vast territory; that its people were loyal to the core; that they lacked population, and wanted people to be sent out to their country—some of the teeming millions which the Association had left at home."

Sir ADOLPHE CHAPLEAU, the Lieutenant-Governor of the Province of Quebec, and the Earl of ABERDEEN having also spoken words of welcome, Dr. J. G. ADAMI, the honorary local secretary of the Association, read the roll of delegates of foreign countries and medical societies, and of the representatives of the various branches of the Association. Certain of these who were present were then formally presented to the Earl of Aberdeen and Dr. Roddick, among them being Professor Charles Richet, the representative of the Faculty of Medicine of Paris, and Dr. O'Donnell, the delegate of the Province of Manitoba. Dr. O'DONNELL being asked by the PRESIDENT to address the meeting gave an invitation to the Association in the name of the Premier of Manitoba to hold an early meeting at Winnipeg, an invitation which will be referred to a meeting of the Council in London.

Dr. RODDICK then delivered his Presidential Address upon Canada in its Medical Aspects, which will be found in THE LANCET of Sept. 4th.

THE SECOND GENERAL MEETING.

The second general meeting was held in the Windsor Hall on Wednesday, Sept. 1st, at 2.30 P.M, the President being in the chair.

Dr. OSLER delivered the Address in Medicine upon British Medicine in Greater Britain, which will be found in full in THE LANCET of Sept. 4th, and upon the proposal of Dr. STEPHEN MACKENZIE, seconded by Dr. JACOBI, a cordial vote of thanks was accorded to him for his eloquent and learned essay.

The meeting was then converted into a Convocation of McGill University for conferring degrees on certain distinguished members of the medical profession, the gentlemen selected for honour being Lord Lister, Professor Richet, Sir William Turner, Professor Michael Foster, Professor Alexander Macalister, Sir Walter Foster, Mr. Christopher Heath, Mr. C. G. Wheelhouse, Dr. W. H. Gaskell, Dr. R. Saundby, the President of the Council of the Association, and Dr. Henry Barnes, the retiring President. These gentlemen were introduced to Lord Strathcona, the Chancellor of McGill University, by Dr. Craik, the Dean of the Medical Faculty of McGill University, in well-chosen terms, and received the degree of LL.D. Lord Lister, Professor Richet, and Professor Michael Foster having spoken briefly in acknowledgment of the great honour done to them, the proceedings closed with the Benediction.

THE THIRD GENERAL MEETING.

The third general meeting was held in the Windsor Hall on Thursday, Sept. 2nd, at 2.30 P.M., when the Address in Surgery upon the Surgeon of Old in War was delivered by Mr. MITCHELL BANKS. An abstract of this address was published in THE LANCET of Sept. 4th.

THE FOURTH (CONCLUDING) GENERAL MEETING.

The fourth general meeting was held in the Windsor Hall on Friday, Sept. 3rd, at 2.30 P.M., when the Address in Public Medicine was delivered by Dr. HERMANN M. BIGGS, Pathologist and Director of the Bacteriological Laboratories, the New York City Health Department. The following is a long abstract of the address, which was entitled:

Preventive Medicine in the City of New York.

After a graceful acknowledgment of the honour he had received by being requested to deliver the address in Public Medicine Dr. Biggs referred to the high position of sanitary science in England, emphasising the fact that she, during the past fifty years, had gone far ahead of every other country in the science of preventive medicine. He referred to the fact that conditions were very different in the United States, for there they had no national Board of Health, and every State did what seemed right to itself; wherefore it followed that there was a great lack of uniformity in regulations, methods, and efficiency. "Instead, therefore," he continued, "of attempting the consideration of the broader subject of public medicine in the United States, I shall confine myself to a discussion of the conditions and methods of sanitary work in New York, as these serve as a type of the best of those found in the greater American cities. The Health Department of New York City is organised under a special Act of the Legislature of New York State and is an entirely independent sanitary organisation, not being subject even to the jurisdiction of the State Board of Health. The Board of Health of the Health Department is composed of four members—namely, the President, who is the chief executive officer; the Commissioner of Health, who must be a physician (these two being appointed by the Mayor of New York City), and two *ex-officio* members—the health officer of the Port of New York (who is a State officer nominated by the Governor), and the President of the Board of Police Commissioners of New York City (the latter being added to bring the Police Department and the Health Department in closer relation to one another). The Commissioner of Health of the Health Board of New York City is *ex-officio* a member of the State Board of Health, as is also the health officer of the Port of New York; so that two of the members of the Municipal Board are also members of the State Board of Health; but the State Board has no jurisdiction in New York City, and the action of the Municipal Board is absolutely independent. The Board of Health of New York City has jurisdiction over the whole of New York City, as it now exists, with its about 2,000,000 of population, and with the beginning of 1898 a similar Board, increased to five members, will have complete jurisdiction over greater New York, with a population of about 3,250,000. All of the administrative and executive work of the department is concentrated at the main offices, and is carried on under the immediate direction of the chiefs of the various divisions into which the department is divided. The Act of the Legislature of New York State creating the department gives to the Board most ample powers, executive, judicial, and legislative in character. The funds for the support of the department are supplied from the general funds of New York City. Before proceeding to a discussion of the management of infectious diseases in New York, I desire to call especial attention to the fact that all matters connected with the scientific investigation, diagnosis, care or sanitary supervision, in every way, of the infectious diseases are regarded by the Board of Health as properly coming within its province. In the development of the methods now in use the proposition expressed has furnished the governing principle. I need hardly point out the great difference between this conception of the functions of a sanitary board and that usually held. The duties of sanitary authorities relating to the infectious diseases are generally regarded as limited to the inspection of reported cases of only a few of the infectious diseases, their removal to hospitals when required, and the subsequent proper disinfection of the premises. In times

Digitized by Google

of emergency, as in the presence of serious epidemics, more comprehensive and stringent measures are considered justifiable; but it has not generally been regarded as necessary or desirable that municipal sanitary authorities should furnish opportunities for, or assistance in, the diagnosis of infectious diseases, should conduct experimental investigations into their causes, should assist in the treatment in any way of cases outside the hospitals, or otherwise concern themselves with these matters. It has seemed to us in New York City, however, that everything connected with the infectious diseases in every form came properly within the scope of the department's work." Dr. Biggs then went on to describe the founding of the municipal bacteriological laboratory in 1892, an institution originally started to investigate cholera, but which very soon took up the questions of diphtheria and tuberculosis. In 1894 the laboratory began the manufacture of diphtheria antitoxin aided by an annual municipal grant of $30,500, and the laboratory now supplies (1) free supplies of antitoxin to all public institutions in New York City; (2) free supplies to private physicians for the use of persons too poor to pay for the remedy, on condition that a report of the cases treated be forwarded to the Health Department on the completion of the case; and (3) free administration of antitoxin to any resident in the city by a special staff of medical inspectors at the request of the attending physician. Besides this work the laboratory also investigates other infectious diseases, such as glanders, in addition to providing for a supply of glycerinated vaccine lymph. The Health Department also provides for disinfection in the case of any infectious disease, the general procedure being as follows: Every case of contagious disease reported to the department is regularly inspected by the medical inspector assigned to the district in which it occurs. When consent can be obtained such cases are removed to the department hospital, and when necessary the removal to the hospitals is enforced. A comparatively small proportion of the total cases, however, are actually treated in the hospitals for contagious diseases. After completion of the illness, or transfer of the patients, thorough disinfection is performed in the apartment, and all infected materials are removed to the disinfection station for destruction or for disinfection by steam. After treatment they are returned to the owner, no charge being made for the services. Disinfection is compulsory in every case.

Dr. Biggs then proceeded to describe more in detail the methods employed in cases of diphtheria and tuberculosis. With regard to the first he said: "Knowledge of the existence of cases of diphtheria reaches the department, either by a direct report of the case by the attending physician or through the forwarding of a culture to the laboratory for bacteriological examination when the case is of doubtful character. If on examination of the culture the Löffler bacilli are found the case is reported to the Division of Contagious Diseases from the laboratories, at the same time that a report is forwarded to the attending physician. In both instances the cases are immediately referred to the medical inspector connected with the Division of Contagious Diseases assigned to the district in which the case occurred. If the person lives in a tenement house, lodging-house, boarding-house, or hotel, and a culture has not been previously made by the attending physician, the inspector makes in each instance a culture to confirm the diagnosis. The subsequent action of the department depends upon the result of this culture. If diphtheria bacilli are found the case is treated as one of diphtheria; if they are absent the subsequent treatment depends on the special conditions existing. In every instance in which the case is proved to be diphtheria, at the end of ten days a secondary culture is made by the attending physician or the district medical inspector to determine whether the diphtheria bacilli are still present in the throat, and subsequent cultures are made at short intervals until the examinations show that the organisms are no longer present. The case is then referred for disinfection, a detailed statement being left at the house by the medical inspector in charge to guide the disinfectors as to the course which shall be followed. Every case of diphtheria which comes to the knowledge of the department is recorded in a card index according to the number of the house and the street in which it occurs, envelopes being used in place of cards. In each envelope, representing always one case, are placed all of the data relating to the first and subsequent cultures and results; and as each case is recorded it is at the same time plotted on a sectional map of New York City drawn to scale, showing every house lot in the city. This plotting is done by conventional signs, so that it is possible at a glance to determine the grouping and distribution of cases in different parts of the city, the number of cases occurring in any given house in the city during the last four years since this method has been in use, and the date when reported. It is also possible in a moment, by reference to the yearly card index, to find all the information in relation to each case which the department possesses. A special corps of inspectors is assigned to the administration of diphtheria antitoxin, and, on request, one of these inspectors will visit a person suffering from diphtheria in any part of the city, day or night, and administer diphtheria antitoxin under the supervision of the attending physician. When the patients are too poor to have an attending physician the inspectors will supervise their removal to the hospitals. These inspectors are also prepared, at the request of the attending physician, to perform intubation in laryngeal diphtheria. It is the usual course, when antitoxin is administered by an inspector, to immunise all members of the family who have been exposed to the disease. Diphtheria antitoxin has also been largely employed for the immunisation of the inmates of public institutions, especially children, when diphtheria has appeared. This is the ordinary routine, and in every instance during the last two and a half years it has been possible to quickly stamp out diphtheria in institutions by this process of immunisation."

With regard to tuberculosis and the methods adopted by the Health Department for its prevention Dr. Biggs referred to the enormous importance of the subject, how it is universally admitted that tuberculosis is both infectious and communicable, and how neglectful sanitary authorities had been hitherto with regard to it. He continued: "The Health Board of New York City first began an educational campaign in relation to the causation and prevention of pulmonary tuberculosis in 1889. In that year a communication on this subject presented by the writer and the associated consulting pathologists of the department was widely published, and leaflets based on it, giving the essential facts as to the nature of this disease, were freely distributed. No further action was taken at that time, as investigation showed that the medical profession and the public were not then prepared for more extended measures. In December, 1893, the attention of the department was again called to the subject by the writer, and it was determined to at once institute more comprehensive measures for the prevention of this disease. The measures then adopted required the notification of all cases of pulmonary tuberculosis occurring in public institutions, and requested reports of cases occurring in the practice of private physicians. They also included arrangements for the bacteriological examination of sputum, to assist in the early diagnosis of this disease, the inspection of all reported cases in tenement houses, lodging-houses, hotels, and boarding-houses, and the instruction of the patients and their families as to the nature of the disease and the means to be taken for its prevention; the inspection of the premises in all instances where deaths were reported as due to tuberculosis, and the issuing of orders, when it was deemed necessary, upon the owners of apartments which had been occupied by consumptives and vacated by death or removal, requiring that such apartments be thoroughly renovated, by cleansing and by painting, papering or kalsomining, before they were again occupied by other persons; and, finally, the education of the public by wider and more comprehensive methods as to the nature of this disease. Placards were attached to the doors to prevent the re-occupation of apartments which had been vacated by death or removal before the orders requiring renovation had been complied with. Under the resolutions by virtue of which these measures were enforced 4166 cases of tuberculosis were reported in 1894, 5818 in 1895, and 8334 in 1896. So far as was possible, all of these cases, except those in private houses, were visited or the premises where they had lived were inspected, and, in addition, the premises occupied by persons dying from tuberculosis (numbering each yearly 6000) were inspected, and such action taken as was considered possible and desirable. Altogether the premises and cases thus coming under observation during these three years numbered more than 35,000. These facts convey some idea of the enormous sanitary importance of the subject. It is conservatively estimated that there are at least 20,000 cases of well-developed and recognised pulmonary tuberculosis now in New York City, and

Digitized by Google

an additional large number of obscure and incipient forms of disease. A very large proportion of the former cases constitute more or less dangerous centres of infection, the degree of danger depending in each instance upon the intelligence and care which is exercised in the destruction of the expectoration. All the suffering and death consequent upon the prevalence of this disease, in view of modern scientific knowledge, is largely preventable by the careful observation of simple, well-understood, and easily applied measures of cleanliness, disinfection, and isolation."

In 1897 the Health Board adopted some recommendations made jointly by Dr. Mitchell Prudden and Dr. Biggs to the effect that pulmonary tuberculosis should be notified in the same way as typhoid fever and diphtheria. Besides this, all public institutions are required to report every case of tuberculosis within one week of its coming under observation and the discharge or transfer of such patient. Dr. Biggs passed on to consider the measures taken for the inspection of milk and meat with reference to the question of tuberculosis, and described how even among the poorer classes the instructions given by the Health Board had resulted in greater care being taken to disinfect sputa, and as far as possible keeping the clothing of the patient apart from that of others. Referring to the medical inspection of school children Dr. Biggs continued: "Early in 1897, under the authority of a special resolution of the Board of Estimate, 150 medical school inspectors were appointed by the Health Board after Civil Service examination. The duties of these inspectors consist in the examination daily, at the opening of the primary and grammar departments of each of the public schools and of the parochial and industrial schools, of all the children who are set apart by the respective class-room teachers as not appearing to be entirely well. These children are examined in each school by the inspector detailed to the school, and are either excluded from the school or returned to the class-room, depending on the result of the examination. Every pupil found to be suffering from any form of general contagious disease, or any contagious disease of the eye or parasitic disease of the skin, is sent home with a written statement to the parents of the cause for the action, and in the case of the eruptive diseases and diphtheria reports are immediately forwarded to the chief inspector of contagious diseases, and by him referred to the various district medical inspectors for inspection and supervision."

Dr. Biggs then gave an account of the educational work of the Board by means of leaflets relating to the prevention of tuberculosis, the care and feeding of infants, the transmission of contagious diseases, and the like. These are written in simple language and distributed among the population, and have proved of the greatest value in bringing about a better state of things especially among the poorer residents. Dr. Biggs then gave some statistical details as to the health of New York City for the past four or five ten-yearly periods, figures showing a steady decline in both mortality and morbidity. As to diphtheria, the mortality had decreased by nearly 40 per cent. since the introduction of antitoxin in 1894. "Finally," said Dr. Biggs, "I believe it may be truly said that there is no great city in the world to-day which, in the broad sense, is cleaner and healthier than New York. By clean is meant the purity of the atmosphere, the cleanliness of the streets, the abundance and purity of the water-supply, and the efficiency of the sewerage system. I wish that so much could be said as to the character of the habitations of the poor, the public baths and public convenience stations, the breadth of its parks and public commons, and the type of its charitable and penal institutions. In many of these respects New York is deficient; but great and rapid advances have been made and are being made in these matters. When it is said that no city is healthier than New York, this statement is made with a consideration of all the sanitary factors in the situation, such as the size and density of the population, the varied nationality of the inhabitants, the character of climate, &c. Nowhere can there be found a fuller recognition than in the United States of England's high standard of excellence in public medicine or a more sincere appreciation of her vast contributions to the progress of sanitary science. But she must look well to her laurels if her cities are to be kept cleaner than the great cities of the United States, and her urban population made healthier and happier than the same class on this side the Atlantic. In the United States we are prepared to adopt, without hesitation, the best that England produces or that the world affords in public medicine, as well as in science, art, and commerce; and, notwithstanding the persistent and determined efforts of our sensational press, the sentiments of the medical profession and of the people at large towards Great Britain are those of sincere respect for her institutions, profound admiration for her great achievements, and warm affection for her people. If I have appeared in this address to have dwelt too long upon and described too fully some of the sanitary methods followed in New York I would urge in extenuation that it has been from a desire that you should know our institutions and methods as well as we know yours, and that through the medium of this great medical association—the largest and most influential in the world—the two great English-speaking nations might in this respect be brought into somewhat closer and more intelligent relations with each other, and thus greater good redound to preventive medicine. Then the people of both nations will live healthier, and therefore happier and longer, lives."

A vote of thanks was heartily accorded to Dr. Biggs for his excellent address.

A letter was received from the American Public Health Association, cordially inviting the members of the British Medical Association to be present at its twenty-fifth anniversary meeting, to be held in Philadelphia in October next.

After one or two formal resolutions the business terminated.

THE SECTIONS.

THE work in the various sections commenced at 9.30 A.M. on Wednesday, Sept. 1st, and in most sections the first proceeding was the delivery of the Presidential Address.

MEDICINE.

The President of the Section, Dr. STEPHEN MACKENZIE, delivered his Presidential Address on Wednesday morning, Sept. 1st, taking for his subject:

The Influences that have Determinsd the Progress of Medicine during the preceding Two and a Half Centuries.

"On this very interesting and, indeed, unique occasion," he said, "when the British Medical Association meets for the first time on Canadian soil, the mind is irresistibly led to compare the condition of medicine at the present day with that which existed when Europeans first settled in Canada and to trace the paths by which progress has been made. When Maisonneuve and his companions landed in what is now the Custom House-square in Montreal in 1642, and when, shortly after, the first hospital was established by the missionary priests, medicine was in a very rudimentary stage. Though anatomy had been prosecuted for some centuries, chiefly on the European continent, it formed no part of ordinary mental education; physiology in the scientific sense was unborn, and organic chemistry not yet created. The medical teaching of that day consisted mainly of the ancient doctrines of the four elements and their corresponding temperaments; of the separate functions of the vegetative, sentient, and rational souls; of the agency of the natural, vital, and animal spirits, that had continued to be taught with very little variation from the time of Galen. It was an age of aphorisms, definitions, systems, and nosologies. Medical opinions were so dominated by theories and burdened by the weight of authority that the phenomena of disease for the most part passed unnoticed and their teachings were neglected. Such knowledge of medicine as the enterprising members of the medical profession who accompanied the early expedition to Canada possessed must have been of the most elementary character, gained by apprenticeship under teachers whose knowledge consisted in the doctrines of Hippocrates and Galen and such crude experience as they themselves had obtained. Without doubt they were as zealous and earnest in their professional duties as we as a profession are to-day, and their treatment was as certainly unfettered and unrestrained by any scepticism as to the theories they had been taught or doubt as to the efficacy of their remedies for disease. But this period was the dawn of a new era in science and medicine. Harvey's great work 'On the Movements of the Heart and Blood' and Bacon's 'Novum Organon,' had recently been given to the world, and the seventeenth century was a time of the greatest activity and discovery in geography and in science. What a gulf separates that medicine of 250 years ago from that of to-day! In tracing

Digitized by Google

how it has been bridged it is right that we should justly apportion the influence that various spheres of activity have exercised in reaching our present position." Dr. Mackenzie then referred to the gradual advance in the study of anatomy. Before the seventeenth century Vesalius and Sylvius, Fallopius and Fabricius had already advanced our knowledge in a great degree. The seventeenth and eighteenth centuries were marked by the researches of Haller, Hunter, Spallanzani, Hewson, and Morgagni, the last-named paying special attention to morbid anatomy. With the beginning of the nineteenth century came Bichat and Malpighi, who, by the aid of the microscope, were enabled to prosecute researches in minute anatomy hitherto beyond the reach of any observer. After referring to the various instruments which nowadays aid in diagnosis, such as the ophthalmoscope, the laryngoscope, the clinical thermometer, and the various applications of electricity, Dr. Mackenzie mentioned the stethoscope and the enormous stride forward taken by Laennec in conjunction with Auenbrugger, who had introduced percussion. "But," continued Dr. Mackenzie, "during the period that bridges the time since Canada first became populated by Europeans to the present day probably no discovery has exercised a greater influence in medical science or conferred more lasting benefits on mankind than the introduction of vaccination by Jenner. It is not necessary in such a meeting to trace how Jenner was led to his discovery. Protective inoculation from small-pox by the introduction of the small-pox matter had long been known in the East and had been introduced into England by Lady Mary Wortley Montagu, but Jenner's rare merit consisted in testing the statement made to him by Gloucestershire rustics by scientific methods and experiments and by waiting for years until the value of the protection, the 'variolæ vaccinæ' introduced by inoculation into the human subject, had been tested by exposure to contagion from small-pox, and until time had elapsed to demonstrate that this protection was no ephemeral influence, but of more or less permanent duration as much as that of an attack of small-pox itself. 'I never expected it would do more, and it will not, I believe, do less,' are Jenner's words. It was not until many years after he had satisfied himself as to the protective influence of the vaccine virus that Jenner in 1796 published his observations. It is needless to trace the effects this discovery has had in saving human lives and in averting the disfigurements with which those who escaped death from the disease were almost invariably afflicted. It is probable that the full significance of his discovery was not revealed to Jenner himself, and, on the other hand, it is possible that he exercised self-restraint in not speculating as to the possible result that might accrue from his remarkable inquiries. Certain it is that the indirect results that have followed from Jenner's discovery that an attenuated virus was protective against contagion from the disease from which the virus was originally obtained have only recently been fully utilised. Probably several causes have been concerned in the want of continuity of progress in this direction, the most important of which has been the difficulty in isolating and handling the virus in many contagious diseases. The investigations into the full extent of the value of inoculation with attenuated virus and derivatives of bacteria have only been commenced in the last few decades since bacteriology has been cultivated by Pasteur, Lister, Koch, Klein, Gaffky, Martin, and others, and the whole subject, with the aid of organic chemistry, made a branch of exact science. Bacteria are now classified by their morphological qualities, by their reactions to staining reagents, by their modes of growth in various media; the temperature at which they grow and at which they are destroyed is determined, their need of oxygen ascertained, the parts of the body they make their habitat studied, the effects of their invasion in the tissues, and the protective powers of the organism observed. The chemical products to which they give rise are isolated, their nature ascertained, and their effects observed on the living body independently of that of the organisms by which they are formed. Finally, the knowledge thus obtained is turned against the bacteria. The virus is attenuated by various methods, often by passing through the body of an animal immune to the disease, and its exact strength is ascertained. It is then used for protective inoculations or for antidotal purposes in those already attacked by the disease from which the virus was originally obtained. Jenner's and the recent researches are equally scientific—observation, induction, experiment; but the differences in carrying out the inquiry on small-pox by Jenner and that of any specific disease due to an organised virus at the present time illustrate my theme of how the progress of medical science has been effected. Great as it has been, and precise, as a rule, as are our methods of research, it is remarkable that up to the present time in two diseases in which protective and curative inoculations have been most conspicuously successful—namely, small-pox, in which we had, thanks to Jenner, the first vaccine; and in hydrophobia, in which Pasteur succeeded in attenuating the virus and using it as an antidote—we have not succeeded in finding the micro-organism that is the true virus, unless, indeed, Monckton Copeman has at length done so in the case of small-pox and vaccinia. As a matter of fact, this organised virus has yet to be discovered in many of the most common specific communicable diseases; but the knowledge gained by the study of some members of this class in animals, and of some—for example, diphtheria—in the human subject, has afforded a basis of knowledge applicable to the whole group. There is one other branch of medical science which has been incidentally alluded to in the previous remarks, but which requires fuller recognition in the survey of the influences that have governed our progress. I allude to experimental investigations in animals. In the seventeenth century in the hands of Harvey and others, but more especially in the eighteenth by the labours of Hunter and others, and in the nineteenth century, this method of observation has been the basis of normal physiology and, later, of abnormal physiology or pathology and therapeutics. These investigations have enabled us to reach a degree of knowledge not obtainable in other ways, not only of value to man, but also to the lower creation." Dr. Mackenzie then passed on to consider the progress of therapeutics, including especially preventive medicine. With regard to clinical medicine he referred to the separation of enteric from typhus fever, a result brought about by the labours of Jenner, Stewart, Murchison, Liebermeister, and the American observer Smart. Relapsing fever had been allotted its proper place owing to the labours of Barker, Cheyne, Graves, Stokes, and Obermeier, who described the specific spirillum in 1873, while another fever parasite—namely, the plasmodium malariæ—had been isolated and proved to be the cause of malarial fever by Laveran, Osler, and others. As to diseases of the kidneys, Cotugno, in 1770, discovered albumin in the urine, but it was owing to the work of Richard Bright that the recognition of diseases of the kidneys was put upon a firm basis. Diseases of the nervous system had been mainly cleared up by physiological and anatomical labours though clinical medicine had lent valuable aid. Dr. Mackenzie then referred to the recognition of Addison's disease and the connexion between myxœdema, cretinism, and the thyroid gland. Owing to the great and undoubted advances in medicine human life had been prolonged and the mortality of most diseases sensibly diminished, although there was an increase of mortality from cancer and some other complaints. In conclusion he said: "The gains have been greater than the losses, and this is not the occasion to discuss why we have failed in this direction. But, whilst the review we have taken of the progress of the science and art of medicine is encouraging, we must remember there will always be a limit to our powers of curing disease. When any part of the higher tissues is destroyed it can never be replaced by the recuperative powers of Nature or improvements in medical science. Sclerosis and destruction of the nervous elements means that they are almost irremediably lost. If the lung is destroyed by tubercle or other disease it can never be replaced. Nothing can make good disintegration of the kidneys or liver. Nor shall we be ever able to retard the effects of time. 'To die is as natural as to be born,' it has been truly said, and the silver cord that chains us to this world must sooner or later give way. Great as have been the improvements in the treatment of disease, our greatest triumphs, in the future as in the past, will consist in the prevention of disease. One of the most important features in modern medicine has been the remarkable development of medical societies and associations, and the fact that they are yearly increasing is strong evidence that the profession finds them useful in its work. They enable us to submit our observations and inquiries, our theories and our practice, to the criticism of those most competent to discuss them, and thus to separate the wheat from the chaff. The meetings of the British Medical Association, amongst others, have been most useful in this respect. Let me conclude by expressing a hope that the work done at this meeting at Montreal, and especially this

Digitized by Google

Section of Medicine, will aid in the search after truth, will stimulate and ennoble the aims and energies of those taking part in its proceedings for the advancement of knowledge and the good of mankind."

Arthritis Deformans.

Dr. JAMES STEWART (Montreal) opened a discussion upon Arthritis Deformans with special reference to its relation to Rheumatism, Nervous Disease, and Tuberculosis. He gave an analysis of forty cases occurring in his practice, and came to the following conclusions. 1. Arthritis deformans is a disease prone to occur in people of a rheumatic tendency who have suffered from subacute rheumatic attacks. The presence of infectious disease of any kind tends to increase this tendency and so do depressing conditions. 2. There is no sharp dividing line between certain cases of chronic rheumatism and the earlier stages of rheumatic arthritis. 3. There is not sufficient evidence to support the views commonly held as to the nervous origin of arthritis deformans. 4. There is no direct relationship between tuberculosis and arthritis deformans. 5. The polyarticular forms of arthritis deformans have clinically the features of an infectious disease. Treatment generally was unsatisfactory. He had found considerable benefit from superheated hot-air baths.

Dr. SHINGLETON SMITH (Bristol) did not believe in the connexion between arthritis deformans and rheumatism. He was inclined to regard the disease as essentially a polyarthritis.

Dr. LINDSAY (Belfast) complimented Dr. Stewart on his lucid and practical paper. He thought the connexion of arthritis deformans and tuberculosis was purely accidental. He had been much struck with the nervous symptoms in arthritis deformans, especially the atrophy of the muscles, and was inclined to regard them as due to peripheral neuritis, perhaps the result of toxic influence. He believed in the connexion between arthritis deformans and chronic articular rheumatism, and had often been at a loss to differentiate between the two conditions.

Dr. OSLER (Baltimore) had been impressed by the nervous symptoms in arthritis deformans. Some of the cases of the disease observed by him had simulated amyotrophic lateral sclerosis.

Professor JACOBI (New York) thought the whole subject was in a very unsatisfactory state, and that we had no real knowledge of any rheumatic condition except acute rheumatism. He was inclined to side with Dr. Osler's views, and to think that arsenic was the best remedy. He complained that no attempt had been made to define arthritis deformans.

The PRESIDENT of the Section thought it probable that several different states were included under the term arthritis deformans. He referred to the opinion of the late Dr. Sutton, who held that arthritis deformans was essentially a disease of debility.

Dr. STEWART having briefly replied, the discussion came to a conclusion.

Dr. TYSON (Philadelphia) read a Note on the proper use of Terms to denote Myocardial Changes.—Dr. FUSSELL (Philadelphia) read a paper on Two cases of Hæmophilia.—Dr. J. B. MCCONNELL (Montreal) read a paper on Pyopericardium following Pleuro-pneumonia; Pericardiotomy; Recovery.

SURGERY.

In the Section of Surgery the President, Mr. CHRISTOPHER HEATH, delivered an address upon—

The Teaching and Progress of Surgery.

After a brief introduction he referred to the two subjects which were to be discussed at this meeting—viz., (1) Appendicitis and its Surgical Treatment; and (2) the Treatment of Cancer of the Rectum, with special reference to the high operation, and then continued: "Nothing, I venture to think, is more remarkable than the recent progress of abdominal surgery. Twelve years ago I was engaged in editing a 'Dictionary of Practical Surgery,' and neither appendicitis nor the operation for removal of the rectum, with which Kraske's name is connected, was mentioned in it, although I had the assistance of the leading London hospital surgeons. Kraske's original paper, I may mention, was published in 1885, and is referred to in Ball's work on the rectum, published in 1887, and in most surgical works since that date. The subject of appendicitis, so far as British surgery goes, dates from a paper read before the Royal Medical and Chirurgical Society in February, 1888, by Mr. Frederick Treves, though the title of it was 'Relapsing Typhlitis treated by Operation.' In August of the same year Mr. Treves opened a discussion on 'Surgical Treatment of Typhlitis' at the meeting of the British Medical Association at Leeds, and subsequently published his address with additions and alterations in the form of a monograph entitled 'The Surgical Treatment of Perityphlitis.' But it is not merely in these two departments that progress has been made. The surgery of the kidney and of the liver has advanced *pari passu* with that of the hollow viscera, and the labours of Morris and Robson in England, and of Keen and others on this side of the Atlantic, have done much for the relief of suffering and the prolongation of life. Looking back over forty years of professional life nothing surprises me more than the change which has come over the treatment of calculus. In my student days to see Fergusson cut for stone by the lateral method was to witness an operation as near perfection as was conceivable, and the dexterity and rapidity with which the calculus was extracted were marred only by the frequency with which death from septic causes spoiled the skill of the surgeon. To have one's first lithotomy was an event in the life of the young surgeon, and every now and then a reputation was spoiled by some *contretemps* in the public performance of the operation. Later, I was the frequent witness of my colleague, Henry Thompson's skill in using the lithotrite to break up the calculus in a series of 'sittings.' Then came 'litholapaxy,' or rapid lithotrity, which we owe to Bigelow, the great American surgeon; and, lastly, that recurrence to the old high or suprapubic operation which was due to the Scandinavian surgeon Petersen. Hence the student of to-day rarely, if ever, sees a perineal lithotomy, and as a consequence his interest in the anatomy of the parts concerned in the operation has greatly diminished. Possibly the surgeons of the last generation laid too much stress upon anatomical details, but it is somewhat remarkable to find how little anatomy seems to serve for practice in the present day. I am told by those who are teaching anatomy now that it is difficult to get the student to take the trouble to make a neat dissection because he can find in the various museums, and notably at the Royal College of Surgeons of England, such beautiful preparations in spirit that he prefers to study from them or from pictures rather than labour to get out the details for himself. If this is so I can only regret that the present race of students is so short-sighted, for without a working knowledge of human anatomy I can conceive of no progress in surgery. But I regret to find that, in Great Britain at least, the teaching of anatomy is gradually getting more and more into the hands of professors who are anatomists, but not surgeons, and that their tendency is to lay stress upon transcendental details rather than surgical relations. But are we not overdoing the scientific teaching of the man who has, after all, to get his living as a practitioner of medicine, surgery, and midwifery? When the medical curriculum was lengthened by a year it was hoped that the additional time would be devoted to clinical work, but I fear that it is by no means always the case, for it is not uncommon for the student to take three years in passing his primary examinations, with the result that but two remain for the study of medicine and surgery. When I became a student of medicine I took to heart the advice of my teacher of physiology, William Bowman, and never allowed a day to pass without visiting the hospital, and though as a lad of sixteen I failed of course to appreciate the importance of all that I saw, yet I saw it, and I can carry my mind back now to cases seen and lessons learned in the early fifties which are of service to me at the present time. But the student is practically forbidden to enter the wards now until he has satisfied the examiners in anatomy and physiology, which he may or may not do in two years, and then there are but three years left for him to study *totam rem medicam*. Far be it from me to decry the modern methods of teaching medicine in the wards of our hospitals. I believe that the care taken to induct every student into the mysteries of auscultation and percussion is beyond praise, and if with some teachers treatment is regarded as of secondary importance, at least the student has the opportunity of studying the *vis medicatrix naturæ* untrammelled under one teacher, and of watching the effects of every new drug upon the human system under another. But all this takes time, and so also the elaborate manipulations of the gynæcological department, the researches of the

Digitized by Google

pathological professor, and all the other teachings of the third and fourth years. And where, then, does surgery come in? Why, I consider myself fortunate if I can secure the regular attendance of candidates for a surgical diploma for the last three months, when their names are put on my list, and I subject them to rigid surgical cross-examination. But if I venture to refer to an illustrative case of last year I find that no one present saw it or even heard of it, though at the time the whole surgical staff may have been in consultation upon it. How, I ask, is it possible for the student to see the serious surgical ailments which are not very common, such as aneurysm, tumours of bone, tetanus, &c., if his attendance in the surgical wards is limited to a few months? And yet there has never been a time of greater activity in operative surgery, not only among hospital surgeons, but among general practitioners, who, thanks to anæsthetics and antiseptics, undertake operations of a magnitude which the hospital surgeon of the last generation would have hardly attempted. Without a knowledge of anatomy, of pathology, and histology progress in surgery is impossible, and it is for those who hold the important positions of teachers in our great medical schools to insist upon a foundation of scientific and practical training being given to our students if they are to become the successful practitioners of the future. The growing tendency of the non-medical teachers of collateral science to regard their particular subject as the one most essential for the medical student must be restrained, and the preliminary period of medical study must be cleared of many obstructions if the student is to have the necessary time to devote to the thorough study of those strictly medical subjects which will fit him to be a sound, practical, and at the same time scientific physician and surgeon."

Appendicitis.

A discussion on Appendicitis then followed, the opening remarks being made by Dr. G. E ARMSTRONG, of Montreal. Dr. Armstrong read a report upon 517 cases seen in the leading Montreal hospitals. This report showed the condition to be most common between the ages of twenty and thirty, and to occur twice as often in males as in females. Discussing the etiology Dr. Armstrong thought that anything that could remove the epithelial lining from the mucous membrane of the appendix might be the starting-point of the mischief. In the total number of cases reported the average mortality was 12 8 per cent.; but from 1853 to 1890, before operation was done—that is, in pre-operative days—the mortality was 23 8 per cent. Of the 517 cases, 389 were operated on and 128 treated without operation. In this latter list the mortality was 3 12. Of 319, 81 were interval cases, in which there was not one death. Of 305 operated on in the acute stage 63 died. The great point in treatment was, Dr. Armstrong considered, to anticipate the severer forms resulting in septic peritonitis by early surgical interference. His rule was to advise operation at the end of twenty-four or thirty-six hours if the patient was not improving.

After some remarks from Dr. WARD COUSINS who credited American teaching and example with having stimulated English surgeons to earlier recourse to operative treatment, Mr. JORDAN LLOYD said that real appendicitis, strictly speaking, was a disease confined to the appendix, and when this was the case there were two sorts: First, those simple cases which got well; and second, those in which the appendix slowly distended with irritating fluid charged with organisms, which fluid made its way through into the peritoneal cavity and gave rise to other forms of the disease with complications. In such cases the physicians and surgeons should see the case together. Early diagnosis was very important, and too much stress, he thought, had been laid on McBurney's point, the localised point of tenderness on deep pressure that is supposed to be diagnostic of appendicitis.

Dr. VANDER VEER (Albany, N.Y.) said he thought that possibly the British surgeons might think the American surgeons were rather too eager to operate.

Dr. W. H. HINCKSON (Montreal) deprecated the too great reliance upon statistics.

Papers were then read upon Ventral and Umbilical Hernia in the same Patient, by Dr. A. E. GARROW (Montreal); upon Traumatic Aneurysm of the Internal Maxillary Artery treated by Ligature of the Common Carotid, by Mr. H. LANGLEY BROWNE (West Bromwich); upon Intussusception of the Vermiform Appendix and Cæcum, by Dr. T. A. MCGRAW (Detroit, Mich.); and upon Lateral Curvature of the Spine treated by Posture and Exercise, by Mr. BERNARD ROTH (Brighton).

The Suturing of Wounds.

A paper was then read upon this subject by Dr. HENRY O. MARCY.

Dr. Marcy stated that, notwithstanding the revolution in surgical procedures, in a large minority of operation wounds made in healthy structures suppurative processes were still to be met with to some extent. The surgical technique was complete for the making of a wound aseptic, but the difficulty was in maintaining it in this condition. He asserted that the cause of this was definite—viz., an open wound. The remedy was to be stated with equal emphasis—hermetically close the wound and seal at the time of operation without drainage. He discussed at length the drainage-tube, its purposes, danger, and in aseptic wounds its worse than uselessness, and referred to the micrococcus pyogenes albus as being in his opinion the most common cause of wounds under abundant antiseptic protective dressings taking on infection when drainage was used, and as being also the cause of stitch abscesses, and the most usual source of infection coming from the surgeon's own hands. Careful disinfection of the hands was of much greater value to the patient than a marble hall for an operation amphitheatre. Dr. Marcy discussed the varieties of suture material and made the deduction that all aseptic wounds should be closed by absorbable sutures under the most careful aseptic conditions. He recommended that sub-cuticular sutures should be used for the coaptation of the skin. The wound should then be dried and sealed with iodoform collodion reinforced by a few fibres of absorbent cotton. He condemned catgut, not so much for the difficulty of sterilisation, as for its inherent defects, a large share of its strength resulting from being twisted and kept dry. When wet, as it must continue to be in the tissues, it was elastic, unreliable in knotting, and untrustworthy. Before twisting and drying it was a very thin, flat band of connective tissue, the fibres of which crossed obliquely for the physiological purpose of accommodating the intestinal contents, and was not unlike a very delicate silk fabric cut diagonally. The advantages to be obtained from the use of connective tissue as a suture material were apparent, not alone because it was absorbable, but because, as Dr. Marcy demonstrated by repeated experimental studies upon animals, it was first surrounded by leucocytes which, little by little, invaded the suture. As the process of absorption went on, these cells were changed into connective tissue corpuscles, and, as a consequence, the suture material was more or less completely replaced by a living band of connective tissue, this of course in many instances proving to be an advantage of the first importance. At first he used the tendons from the buffalo, moose, and caribou, the advantages of which he emphasised in a paper read at the International Medical Congress in London, in 1881. Such tendons had been used from time immemorial by the North American Indians, for the sewing of robes. The following year, Dr. Marcy, as the result of systematic and extended observations, ascertained that the tendons taken from the tail of the kangaroo were greatly to be preferred, since they were smooth, even in any variety of size, had never been subjected to decomposition, and were much less difficult of sterilisation, while in strength they exceeded in equal weight that even of silver wire. When properly chromicised they held in the tissues for about three months. They were now so generally used and well known that only reference to them was required. Coaptation and fixation at rest, with as little force as possible, of like structures was the object sought. Suture material more than required to secure this purpose was detrimental. It must be applied with a minimum of devitalization of the tissues. The interrupted suture was faulty in that it held at only the single joints of insertion, and in order to coaptate the structures in large wounds undue compression, often to devitalization of the part constricted, had to be used. Each stitch required a knot, which was slow of absorption. Like structures, as far as possible, should be joined, fascia to fascia, muscle to muscle, &c. When coaptation had been accurate there were no pockets left for the undue retention of fluids, and as a consequence no drainage-tube was required. Dr. Marcy much preferred the full-curved Hagedorn needles, since they penetrated the tissues with ease and accuracy and might generally be used without the intervention of forceps. The continuous suture required but a single knot, and undue constriction was less liable, since a

Digitized by Google

compensation occurred equalising the force applied to the entire suture. As a rule fatty structures should not be sutured, since necrosis is not seldom a resultant. The over and over (glover's) stitch was faulty in that it constricted the tissues unduly. Dr. Marcy applied the suture deeply from side to side, the needle being introduced parallel to the long axis of the wound, and he therefore called it the "parallel suture." The needle was inserted exactly opposite the emergence of the preceding stitch and, when drawn upon, it would be noted that the surfaces were evenly coaptated, and that the suture was deeply implanted in healthy tissues, crossing the wounded edges at right angles. The sub-cuticular suture was effected in precisely the same manner and the wound sealed. An aseptic wound thus closed with buried aseptic tendon sutures would remain aseptic, and in well vitalised structures was followed by primary union. No expensive and troublesome dressings were required. The subsequent nursing and care were very greatly diminished. The anxious foreboding of the surgeon lest "something should go wrong with the wound" was avoided. No stitches were to be removed, reducing greatly the dread and anxiety of many patients. Safety was greatly enhanced and the period of convalescence shortened. When the work had been done with care the resultant cicatrix was often scarcely visible—a matter of much importance in some parts of the body. Some operations hitherto impossible had been rendered feasible by the use of the buried absorbable suture—e.g., the restoration of the obliquity of the inguinal canal in the male upon which was dependent the cure of hernia. Indeed, it was for the cure of hernia that Dr. Marcy first used buried animal sutures in 1870. He recently reported to the American Medical Association that he was in his four hundredth series of hernia operations, with over 90 per cent. of resultant cures. In laparotomy the closure of the abdominal wound was greatly strengthened by the use of aseptic absorbable sutures. It was estimated that 10 per cent. of laparotomies, where the wound was closed by a single line of deep interrupted sutures, were followed by hernia. Dr. Marcy reported more than 500 cases of aseptic laparotomies in his practice with but a single resultant hernia. In concluding he urgently recommended that every surgeon should familiarise himself with the method of wound closure by means of buried absorbable sutures, preferably tendon, predicting that these would soon be generally adopted, and that they would hold the first place in the technique of modern treatment of wounds.

PUBLIC MEDICINE.

The Presidential Address was delivered by Dr. E P. LACHAPELLE, President of the Board of Health of the Province of Quebec, his subject being

The Progress of Sanitation in Canada.

After some words of welcome to his audience, Dr. Lachapelle gave a brief review of the hygienic measures introduced under the French *régime* (1603-1763). In 1667 Louis XIV. of France established for the Civil State a system of registration which is still in force in the Province of Quebec, the registers of baptisms, marriages, and burials being kept by the clergy, who furnish the civil authorities with copies. The British domination commenced in 1763, but under it there was no permanent health legislation up to 1867—that is, until the period of Confederation. Dr. Lachapelle continued: "With the advent of Confederation we enter a period of positive systematisation. The British North America Act defines the respective rights and powers of the Federal Government, as well as those of the Provincial Governments, and we will now review in a detailed abstract the laws successively enacted at Ottawa and in the different provinces. All matters relating to foreign countries and to commerce are of federal jurisdiction, and accordingly, ere the first year of the Confederation (1868) the Federal Government enacted an Immigration Act destined to be completed later (1871) by the Quarantine Act, and rendered most effective by the laws of 1893. Actually, our ports are protected by eight well-organised quarantine stations: Grosse Isle (Quebec), Halifax (Nova Scotia), St. John (New Brunswick), Sydney (Cape Breton), Hawkesbury (Nova Scotia), Chatham (New Brunswick), Charlottetown (Prince Edward Island), and William Head (British Columbia). The quarantine organisation is under Ottawa's exclusive control, but on other questions (vital statistics, contagious diseases in animals, food adulteration) the provinces have a concomitant jurisdiction. In most of the provinces of the Dominion of Canada the local legislature has, by a statutory law, delegated its powers to a Provincial Board, charged with enforcing sanitary measures, and in whom, consequently, lies the authority. The law, however, varies on this matter in different provinces. Ontario and Quebec are, perhaps, the best-managed provinces; in any case, they are the ones in which the organisation is the oldest. We will examine them conjointly. The Provincial Board of Ontario was founded in 1882, that of Quebec in 1886. It is those two boards that have enabled public hygiene to make the greatest progress in Canada. In Ontario compulsory vaccination of all children over four months of age has been provided for by the statute, and school teachers may require a certificate of vaccination from intended pupils. The Provincial Government has the entire control of vital statistics (1896), the compiling being done directly by the secretary-treasurer of each municipality. Finally, the Food Act, very explicit in regard to cities, renders more definite the federal laws on food adulteration and specifies their bearing. In the Province of Quebec vaccination is obligatory by statute in four cities, but any other municipality may render it compulsory. The keeping of the registers of the Civil State is still, as in the days of Louis XIV, confided to the care of the clergy of whatsoever denomination, and it is from those gentlemen that each month the Provincial Board of Health receives the certificates establishing the causes of death and those reporting the marriages and births. From these reports the Board compiles its statistics. Regarding the adulteration of foods, the Provincial Board has power to make regulations to supplement, in a certain measure, the federal laws. In relation to the prevention of contagious diseases, hygiene in factories, sanitation in general, and the suppression of nuisances, the Quebec Provincial Board has issued permanent and very precise regulations, and has formulated in them a standard of effectiveness that must be attained by the municipal boards. In both Ontario and Quebec the Provincial Boards may exercise the powers conferred upon the local boards, if such local boards neglect or refuse to perform their duties. New Brunswick (1887) and Nova Scotia (1893) possesses somewhat identical organisations, the Lieutenant-Governor in Council having the right to legislate on sanitary matters. The municipal boards in both these provinces enjoy similar powers; only in Nova Scotia the Lieutenant-Governor can put his veto. The sanitary laws of New Brunswick (1887-88-89) very much resembled those of the province of Quebec, as they confer on the Provincial Board the power to make regulations respecting the prevention of contagion, the inspection of food, and of insalubrious industries, drainage, and the repression of nuisances. The Registration Law (1887) provides for the publication of vital statistics. In Nova Scotia the authority of the provincial board with regard to contagious disease is simply advisory; it may, however, during an epidemic, substitute itself to inefficient municipal boards. Manitoba (1893) admits of a special organisation which seems to suit the needs of a country whose population is dispersed over a vast extent of territory. Its Provincial Board is composed of five members—a veterinary surgeon and four physicians. For the needs of local administration the four physicians are titled "inspectors," and the province is divided into four districts. In each of these districts the authority of the inspector is supreme: he may, if he believes it necessary, set aside all orders and by-laws enacted by local authorities. British Columbia has (1895) a Provincial Board which, according to the statute, seems to be only advisory, but which, nevertheless, has established very complete and very effective regulations. We will even point out a measure that surpasses those of any other provinces: it is the prohibition of discharging sewage into any river. Prince Edward Island has no provincial board. It has a good law respecting vaccination, and by its Health Act local boards are appointed in two cities, and the Lieutenant-Governor in Council is empowered to appoint a Board of Health in each county. In the North-west Territories a law relating to hygiene was passed in 1882. Its objects are only preventive. The Lieutenant-Governor can hinder any person within the Territories from leaving a locality in which there exists a contagious disease. He can also delay at the frontiers any suspicious outsider. He can divide up the Territories into sanitary districts and appoint medical health officers if he judge such measures expedient. Canada, with regard to hygienic matters, is therefore advancing rapidly in the path of progress."

Mandatory Measures in dealing with Measles, Whooping-cough, Tuberculosis, and Leprosy.

Several papers were read on this subject, among the authors being Dr. P. H. BRYCE, Secretary of the Provincial Board of Health, Ontario; Dr. C. O. PROBST, Secretary State Board of Health, Ohio; and Dr. H. HANDFORD, of Nottingham, England.

Dr. BRYCE'S paper was a lengthy one. He discussed measles, scarlet fever, whooping-cough, and tuberculosis. After citing statistics he advocated the closing of schools when scarlet fever and measles were prevalent in epidemic form. The use of notification cards and isolation were dwelt on at length. He was in favour of compulsory measures and the early removal to hospital in cases of measles and scarlet fever. He spoke of leprosy in the United States of America as having caused sixteen deaths. In Canada it did not seem to have any significance. He knew of, and referred to, the Leper Asylum at Tracadie, and said that if the disease was contagious segregation was necessary. With regard to isolation in tuberculosis, the danger was from the bacilli; they might live for a year Houses which had been occupied by consumptives should be disinfected. Tuberculosis was a contagious disease and great care was necessary. The sputum should be disinfected.

Dr. PROBST went over much of the same ground. For men in the American Navy he recommended early recognition of the disease and special hospitals. Any plan for the prevention of tuberculosis must consider the liability of animals to infection and the question of infected milk. Regarding the care of herds of cows, the healthy animals should be separated from the unhealthy. Calves born of unhealthy cows should be separated and fed on healthy milk. The bad ventilation of stables was responsible for much of the disease among cattle.

Dr. HANDFORD, in his opening remarks said that there was no want of legislation in England regarding such matters, but they did want a Minister of Public Health. Many advances must be made in hygiene and public health. Regarding mandatory measures in England compulsion had completely failed. The people must be educated, their confidence must be gained. The education of the wealthy in such matters was as necessary as the education of the poor. In Nottingham no case of scarlet fever had ever been removed to a public hospital on a magistrate's order. As a result of eight or ten years' observation 90 per cent. of the cases of scarlet fever were now voluntarily sent to the hospitals in his district.

Dr. OLDRIGHT (Toronto), Dr. WOLFRED NELSON (New York), and Sir JAMES GRANT (Ottawa) also spoke.

OBSTETRICS AND GYNÆCOLOGY.

The Presidential Address in this section was delivered on Thursday, Sept. 2nd, by Dr. W. JAPP SINCLAIR, Professor of Obstetrics and Gynæcology, the Owens College and Victoria University, Manchester, who selected as his subject

The Injuries of Parturition: the Old and the New.

Dr. Japp Sinclair began his address by telling the sad story of two healthy primiparæ who in the course of normal labour had received serious injuries from the use of forceps. He then compared this sort of haste with the helplessness of ancient obstetric practice which allowed women to die in prolonged labour without making an attempt to save them. He then proceeded to divide the century and a half which has elapsed since the introduction of the forceps to the present time into three periods: first, from the introduction of the forceps to the discovery of anæsthetics, about a century; secondly, from the discovery of anæsthetics to the introduction of antiseptics, a quarter of a century; and, thirdly, from the general introduction of antiseptics in midwifery practice to the present time, very nearly a quarter of a century. "Now," continued Dr. Sinclair, "if we consider our present position, we have much to congratulate ourselves upon, and yet we may fairly ask if there is not much room for improvement in the use which we make of our resources. Is not one of the most remarkable things in the history of medical science during the last quarter of a century the extraordinary development of gynæcology in its surgical aspect? Gynæcology flourishes and has become largely surgical—so largely surgical that Sir W. O. Priestley, my predecessor of two years ago in the position which I occupy to-day, addressed to the Obstetrical Section a warning and a remonstrance on the too free application of surgical methods to gynæcology. Midwifery has during the same period become also largely surgical—too surgical—and a thesis which I shall endeavour to maintain to-day is that gynæcology has become so largely surgical as the direct result of surgical interference in midwifery practice; the accoucheurs are the providers of material for the gynæcologists. I fully appreciate the admirable work done during that time by gynæcological surgeons in dealing with the new growths of the sexual organs, and I do not decry it; but for the material of his ordinary daily labour the gynæcologist has to look to the accoucheur. Last year Dr. Cullingworth did a good service to the medical profession by addressing the Obstetrical Society of London on the subject of the undiminished childbed mortality in England in spite of our advantages and improved methods of practice. But in addition to the avoidable childbed mortality, there is the very serious question of childbed morbidity, which I maintain and repeat is largely owing to the prevalence of surgical methods in the practice of midwifery. The term 'surgical' is employed here with almost exclusive reference to the use of midwifery forceps. It was said by Baudelocque that the midwifery forceps was the most useful surgical instrument ever invented, and with that strong and unqualified opinion we are all more or less in agreement. But, like all our powerful remedies, the forceps must be used with circumspection, else disastrous consequences must ensue." Dr. Sinclair then gave an interesting *résumé* of the practice of Smellie and Robert Collins, and continued: "The typical injury of parturition during the first period—i.e., before the discovery of anæsthetics—was vesico-vaginal fistula, but there can be no doubt that the not infrequent use of perforating instruments and the crotchet produced bruises and lacerations which, in pre-antiseptic days, must have conduced considerably to the maternal mortality. The mistaken practice also of 'stretching the birth,' which I am afraid is by no means a thing of the past, was so prevalent that it must have done infinite injury. By causing minute necroses or lowering the vitality of the tissues it must have opened up the way to bacterial invasion with all its consequences. Laceration of the perineum must have been occasionally inevitable in former generations as in our time. But special attention appears to have been given to its prevention. Denman, indeed, refers to its prevention as 'the principal object of our attention in natural labours.'" The second period, commencing with the discovery of anæsthetics and ending with the general introduction of antiseptics, Dr. Sinclair dismissed somewhat more briefly. "The introduction of anæsthesia did not," he considered, "lead to any great improvement in the practice of obstetrics. The medical practitioner could now relieve the patient from the worst pangs of parturition, and therefore could well afford to wait in normal labour for completion by the natural process. But it was soon found that the production of anæsthesia was not all gain. It was found that the prolonged administration of chloroform brought on inertia of the uterus, tedious labour, and post-partum hæmorrhage. The tediousness of the labour made the 'gossips uneasy,' and the most conservative of practitioners was too often driven to the application of the forceps. In fact, the consciousness that the final pangs of labour and the acute suffering which would otherwise be produced by the application of the forceps could be entirely relieved by the administration of an anæsthetic had for its practical effect a great extension of operative midwifery. Lacerations of the perineum became much more frequent than under the old practice of delay, and as it was quite unusual to suture these lacerations, as is now the universal practice, incontinence of urine owing to vaginal sloughing was replaced by incontinence of fæces resulting from complete laceration of the perineum. The lacerations of the cervix and vagina and their relation to parametritis were either unobserved or not understood until Emmet taught the medical world their importance. Just as the practice of the first period made material for the special beneficent work of Marion Sims, the abuses of the second period provided the opportunities which Emmet had the genius to recognise and to use. The advent of the third period—that of anæsthetics combined with antiseptics—dates from 1870 to 1873, or somewhat later. About that time began those triumphs of abdominal and pelvic surgery applied to the diseases of women, of which men of our special branches of medicine are so justly proud. The

Digitized by Google

operations in general surgery also took on a new phase, and our students, accustomed to witness in the hospital the audacity with which the modern surgeon, depending upon anæsthetics and antiseptics, could deal with new growths and surgical injuries, were influenced, perhaps almost unconsciously by what they had seen of operative surgery, into applying its methods to midwifery practice. There has been little of precept and example to counteract this tendency. Our students in the medical schools are not taught obstetrics and gynæcology in a reasonably practical way; while, on the other hand, they apply themselves to surgery, theory and practice, from the time they pass the entrance examination until they graduate. They learn surgery which they will never practise, and they will practise midwifery which they have never learned." Dr. Sinclair then gave the following picture of the young practitioner. "The young practitioner sees a woman suffering under the pangs of labour; he can relieve these by anæsthetics: normal labour is a process which requires time; the practitioner does not like waiting, and he has appliances by which he can abridge the process of normal labour: he knows that he may produce injuries, but these are in his eyes trifling compared with the injuries which he has been accustomed to see treated successfully by the surgeon with the aid of antiseptic appliances, and a laceration can always be sutured if it appears to be of sufficient importance. Why, therefore, should he permit suffering to his patient and waste his own time? He does not know enough of gynæcological practice to be impressed with the importance of a laceration of the cervix or vagina or a dislocation of the uterus—that is to say, of the remoter consequences of his well-meant interference. More than that, although he may have attended the statutory number of labours required by his college or university, he has enjoyed few advantages of direct practical instruction and example; he may be unable to diagnose the presentation, so he must trust to force alone; he has seen little or nothing of the puerperal state, so he is hardly in a position to appreciate the risk to his patient or to recognise some of even the immediate effects of operative midwifery." The next step in Dr. Sinclair's argument was to allow that before passing judgment on this kind of practice as to whether it is reasonable, or unavoidable, or praiseworthy, or the reverse of all that, we must find a criterion of good practice. To which end he read to the section the figures showing the details of two years of the practice of the Manchester Maternity Hospital. From these figures it was evident that the forceps deliveries among in-patients were in a comparatively high proportion, but the hospital beds are understood to be retained for cases of difficulty and danger; hence a large proportion of the women admitted have a history of difficult or operative labour in the past. The proportion of forceps deliveries among these in-patients was almost exactly 9 per cent., and no woman died after the use of the forceps. The proportion of forceps deliveries among the home patients in the charge of the midwives might be considered the normal requirements of the community. "Now, in 2049 home-patient deliveries," said Dr. Sinclair, "the forceps had to be applied by the obstetric physicians twenty-nine times; that is as nearly as possible 1·4 per cent. I have already called your attention to the fact that within the same area of population, but among the class of people who can afford to pay for private medical attendance, the proportion of forceps deliveries is 25 to 30 per cent. Such a striking contrast surely supplies food for reflection and calls for explanation." Dr. Sinclair concluded by quoting many continental figures in support of his proposition that delivery by forceps is nowadays far too common.

The Vomiting of Pregnancy.

On the previous day, Wednesday, Sept. 1st, a discussion took place on this subject, introduced by Dr. J. A. TEMPLE, (Toronto), in which Dr. W. GARDNER and Dr. J. C. CAMERON (Montreal), Dr. R. B. MAURY (Memphis), Dr. SKENE and Dr. C. JEWETT (Brooklyn), and Dr. H. T. HANKS (New York) joined.

Dr. GILES showed for Dr. ROBERT BARNES (London) a Drawing to illustrate Barnes's Boundary Line in Placenta Prævia, and Dr. BERRY HART (Edinburgh) and Dr. WRIGHT (Toronto) discussed the matter. — Dr. JOHN CAMPBELL (Belfast) read a paper on Labour Complicated by Abnormalities of the Cervix Uteri and Vagina, and the subject was continued by Dr. MURRAY (New York), Dr. HOWARD KELLY (Baltimore), and Dr. JEWETT (Brooklyn).—Dr. W. C. LUSK (New York) gave a Contribution to the Study of the First Stage of Labour from a Frozen Section, illustrated by drawings, photographs, and plaster casts. — Dr. BERRY HART complimented Dr. Lusk on his excellent piece of work. — Dr. W. GARDNER showed a specimen of Vesical Calculi removed from the Bladder in a case of Procidentia.

PHARMACOLOGY AND THERAPEUTICS.

The Presidential Address in this section was delivered by Dr. D. J. LEECH, Professor of Materia Medica and Therapeutics at the Owens College, Victoria University, Manchester, who took as his subject:

Past and Present Views as to the Actions of Medicines.

Dr. Leech opened his address with a summary of the views held during the last sixty years as to the action of medicines, quoting Pereira, Headland, Brodie, and others. He then gave a sketch of the progress of pharmacology during the same period, continuing as follows: "The knowledge of the method in which drugs remove the cause of disease and counteract its results did, indeed, greatly increase; so, too, did our power of lessening suffering; but something more was required. We could not combat the evils produced by disease at all essential points of attack, and our power to stay its progress was therefore very limited. And no way was made in the discovery of substances capable of generally antagonising the functional changes and pathological conditions characteristic of special forms of disease. No drugs were found acting as mercury does in syphilis, and the method of action of this and also of some of the best known of our remedies has remained undetermined. But in very recent times, owing to the investigations of pathologists and physiologists, light has come. The discoveries made concerning the curative influence of certain animal substances such as thyroid gland and concerning toxins and antitoxins, mark a new departure in therapeutics. How do they affect existing views concerning the action and uses of drugs? Strong views have recently been expressed on this point. Dr. Saundby, for example, considers that though the recent discoveries with regard to pathogenetic organisms and their products open up to us an altogether new prospect in therapeutics, the system of pharmacology is about to pass into the limbo of the forgotten, and Professor Behring, of Marburg, thinks that in the light of serum treatment all our older views must vanish. Cellular pathology, he says, has become unfruitful for therapeutics; it is vain to treat the organs which are affected. Serum treatment, if we may judge from the *résumé* of his paper which was read at the recent 'Congress für Innere Medicin' at Berlin, is alone efficient. If Behring's view as to its nature is correct its study is almost outside the boundaries of pharmacology, for he holds that antitoxin is not a definite chemical compound, but a quality, inherent in certain albuminous substances as magnetism is in the magnetic oxide of iron. If antitoxins are powers, not substances, we are almost carried into a new world in which pharmacology, as at present understood, has no place. There seems little probability that the view of the enthusiastic supporter of serum treatment has any real foundation, and as I do not know the reasoning which has led to its adoption I shall not attempt to controvert it. The toxins disturb the functions of the various organs like other pharmacological agents. They have a definite physiological action, and there is no reason for believing that they act on tissues in a manner fundamentally different from other medical agents. They have, indeed, a more marked power than most drugs in producing immunity. It is impossible to say whether in this respect they act like ordinary drugs, but it can hardly be doubted that they produce their effects in a similar, if not in the same way. Another property which toxins have has not been shown to be common to the medical agents hitherto employed. They lead to the production of antitoxins, but how we know not. Protoplasm has the power of altering substances which come in contact with it, and it is possible to imagine that by some subtle chemical influence the toxin is converted into a substance directly antagonistic to it in physiological properties. But it seems far more probable that antitoxins are produced by the protoplasm itself under the influence which the toxin exerts upon it. It is shown that the serum of blood does contain a bactericidal substance, and many years ago Hankin pointed out that the blood of certain animals normally contains what he calls a 'defensive proteid,' to which Buchner subsequently gave the name of 'Alexin,' and which practically is an antitoxin. If cell protoplasm has the property of thus

Digitized by Google

normally producing such defensive material it is not difficult to imagine that under the influence of certain toxins it may produce special antitoxins Although we have no proof, so far as I am aware, that any of the older used drugs lead to the production of antitoxins, there is reason to believe that certain vegetable albuminoids are capable of doing so. Ehrlich states that the toxalbumins, ricin and abrin, derived respectively from castor-oil and jequirity seeds, not only cause immunity, but the formation of an antitoxin in the blood which protects from the poisonous influence of these two substances. The methods in which antitoxins act are as yet shrouded in obscurity. They may be to a certain extent destructive to the organisms giving rise to disease, as quinine probably is in ague, but they seem to produce their special effects by antagonising the toxins these organisms produce, and they differ from the older drugs in exercising a wider and more rapid influence. They seem to antagonise the toxins at once at all essential points instead of counteracting their effects at one or two points only. There is good reason for believing that they do not neutralise each other as an acid neutralises an alkali. At least Calmette has shown that neutralisation does not obtain in the venins and antivenins the action of which very closely resembles the toxins and antitoxins, for he finds that if a mixture of venin and antivenin, which is non-toxic because of the antagonistic influence of the two substances, be exposed to a temperature of 68° F. the power of the antivenin is destroyed, but not that of the venin, which now can exert its toxic influence. It seems probable that the antitoxin acts on the molecules of the protoplasm in some way and prevents the toxin exerting its ordinary influences. It is the combination of pharmacology with therapeutics which gives the value to the work of this section, and we shall have several important discussions which will probably illustrate this. That on the treatment of syphilis will show the difficulties we labour under from defective knowledge of disease and drug action, but it will show, too, how patient observation, long continued, may to some extent make up for such defective knowledge. For nearly 300 years the use of mercury in syphilis has been debated, but because the nature of syphilis and the action of mercury were quite unknown the utmost divergence of opinion existed in earlier times as to its use. On both points some knowledge has been gained, and differences in view are not now so wide as heretofore, yet we shall probably find that on some points observations have led to very different results. The discussion of the treatment of insomnia will illustrate our indebtedness to the combination of pharmacological and chemical knowledge, since for most of our new hypnotics we are indebted to this joint working. The third subject for discussion—diuretics—has in recent years been illumined by pharmacological investigations, which though they may not have cast fresh light on the effects and importance of increasing kidney secretion, in certain forms of disease have nevertheless made more clear the manner in which diuresis may be brought about."

The Treatment of Insomnia.

Dr. C. K. CLARKE (Kingston, Ontario) opened a discussion on this subject. He first treated of the physiology of sleep. Cerebral anæmia, vascular dilatation of the skin, and lessened blood pressure might be considered as common conditions in sleep. Sée's classification of sleeplessness was cerebral, spinal, and psychic. Want of sleep killed more quickly than starvation. In treatment let drugs remain to the last. Try the warm bath, 104° F., and cold to the head. Patients often fall asleep in the bath. Hot milk and the sun bath were good, also hot ale at night. In the insomnia of neurasthenics, strychnine and digitalis were often effective. In sleeplessness from pain he considered morphia almost unavoidable.

Dr. R. W. WILCOX (New York), Dr. A. MCPHEDRAN (Toronto), and Dr. E. T. EDES (Jamaica Plains) continued the discussion.

Professor RICHET (Paris) discoursed on hypnotics in general and chloralose in particular. He made use of the blackboard to impress some of his points. He considered that changed blood pressure was not the basis of sleep production. In the study of chloralose he had found that this body did not produce collapse, but rather a strychninisation of the cord; the brain might be congested. The drug might be used in heart cases up to six grains. Slight convulsive jerks might occur, but there was no danger. In one case a patient, a woman, wilfully took sixty grains, there was deep sleep and starting like a strychnine case. In thirty-six hours there was complete recovery. Professor Richet used chloralose by preference.

Dr. DONALD MACALISTER (Cambridge) related his experience among students. The causes here were principally overwork and anxiety about examinations. He eschewed hypnotics, and succeeded in most cases. He first advised a cold bath for either sex, then walking about the bedroom naked till quite cold, or failing in this, next night put on a wet nightshirt, and over it the "blazer." He also suggested reclining in a hammock, thus exposing to the air the lower half of the reclining body. In the case of overworked students too tired to sleep strychnine might be tried, hot coffee also. Magnesium sulphate was an ancient but trusted ally in therapy. As a *dernier ressort* he recommended chloralamide, but it should be given without the patient knowing what he is taking.

Dr. ROBERT SAUNDBY (Birmingham) believed chloral to be the most certain pure hypnotic. The dangers had been exaggerated. Sulphonal had been used to an enormous extent in England, and yet hæmatoporphyrinuria was almost unknown.

Dr. J. Y. A. CAMPBELL (Carlisle) spoke of insomnia in the sane and in the insane. From long asylum experience he found chloral the surest sleep producer. He thought well of paraldehyde. The great thing was to secure sufficient outdoor exercise and suitable diet. In the sane the great desiderata were change of air and change of scene. He was doubtful of the great danger of chloral, as he had seen 8 drachms used at one time without evil effect, and had given as much as 4 drachms.

Dr. W. WHITLA (Belfast) approved of leaving drugs to the last. Millions of doses of sulphonal had been administered with very few accidents. Chloral he considered to be dangerous and the addition of digitalis useless. He was favourable to alcohol. From two to two and a half ounces of proof-spirit with hot water at night was enough. So small a matter as an uncomfortable pillow might cause a bad night.

Dr. EDWIN RAYNER (Stockport) said that there were idiosyncrasies and therefore no general rules. He liked small doses, as 10 grains of chloral, or 10 grains of sulphonal combined with 5 grains of phenacetine.

The PRESIDENT of the section summed up the discussion of the first day's session, noting that there was a unanimity of opinion that every case must be thoroughly studied for the discovery of abnormal conditions, the presence of which must be known before a reasonable therapy could be applied.

Dr. C. R. MARSHALL (Ferndale) had a fine display of Indian hemp and its principles on the table for inspection.

PATHOLOGY AND BACTERIOLOGY.

The Presidential Address in the Section of Pathology was delivered by Mr. W. WATSON CHEYNE, Professor of Surgery in King's College, London, who took as his subject

The Progress and Results of Pathological Work.

"On such an occasion as this," said Mr. Watson Cheyne, "one is naturally tempted to look back on the history of pathology during the last sixty years, but I hope that you will not expect me to follow the fashion in this respect. To trace the history of pathology during the last sixty years would be to follow the science practically from its commencement and to go back to a state of matters which it is almost impossible for us now to realise. To-day it is the etiological side of pathology, so to speak, which occupies our attention, and deservedly so, for, so far as practical results in the treatment of disease are concerned, the knowledge of the changes produced is of comparatively minor importance as compared with that of the reason why they are set up and how they take place. The more accurately we can trace the etiological factors in disease and the subsequent course of events the more likely are we to arrive at a rational method of treatment. The most striking and important advance has been the growth of the great science of bacteriology, a science which has not only led to most important practical results, but has also thrown a flood of light on the processes which go on in the body as a whole and has stimulated research in other directions not immediately associated with it. It is difficult for those who have only taken up the subject of bacteriology comparatively recently to realise the absolute blank which it presented even twenty years ago. When I

Digitized by Google

became house-surgeon to Lord Lister in 1876 objections of all kinds were urged against the theory on which Listerism was based; some denying the existence of bacteria at all, others maintaining the theory of spontaneous generation; some asserting that organisms were always present in the healthy tissues, others denying that they had anything to do with disease, or that the success of the antiseptic principle depended in any way on the exclusion of micro-organisms from wounds. A great advance which followed soon afterwards was the remarkable research by Lord Lister on the bacterium lactis, in which he devised a method of separating bacteria by fractional cultivation, which resulted in the separation of the bacterium which causes lactic fermentation from other organisms. Then came Koch's work on infective diseases of wounds and Metchnikoff's work on phagocytosis, a theory which is not only very fascinating in itself, but which has proved a most suggestive working hypothesis leading to many of the researches which have given bacteriology its present position. In spite, however, of all that has been done many problems still remain unsolved. In the case of tuberculosis, why is it that in one part of the body we have a slow growing lupus disease and in another part, perhaps, of the same body a rapidly developing tuberculosis? The same problem is apparently presented with regard to the bacilli of diphtheria, in that we may have in one case a true diphtheria, in another a membranous rhinitis, while in a third, although the bacilli are present in the throat, the individual may be apparently healthy. Another very remarkable problem is presented by the results which follow free incisions into tuberculous tissue. An incision is made into the abdominal cavity, masses of tuberculous tissue and tubercle are found scattered over the peritoneum, nothing whatever is done, the wound is stitched up, and yet in many cases the patient, who up to that time has been going steadily down hill, begins to pick up, and the disease may come entirely to a standstill. In connexion with the pyogenic organisms also we have many problems. How is it, for example, that after an abscess is opened antiseptically suppuration at once ceases? If instead of opening the abscess antiseptically a poultice be applied, suppuration goes on and may be very profuse. But if it be opened at a time when there is free fluctuation and when it is beginning to point, and if the necessary antiseptic precautions be taken and proper drainage provided, no more pus forms, and yet when the abscess is opened it is found to contain living pyogenic organisms. We can easily understand that the subsidence of the fever and general disturbance is due to diminished absorption of toxic products. But why do not these living pyogenic organisms keep up the suppuration? And why is it that after two or three days one may fail to obtain any cultivations from the serum which escapes from the wound?" Mr. Watson Cheyne here discussed the pathology of inflammation, arguing that inflammation and healing are two different, and, indeed, to some extent antagonistic, processes, and that although in every wound the tissues in resenting the injury show the early stage of inflammation, yet if no organisms be admitted the inflammatory phenomena soon pass off, and where there is destruction of tissue a second process—namely, that of repair—begins. He continued: "A very remarkable thing in connexion with these advances, especially in experimental pathology, is the enormous direct practical benefit which has already resulted to the human race; and it is sufficient answer to the antivivisectionists who oppose the use of intelligence and observation and experiment to point to the saving of human life and the relief of suffering which has taken place in the last few years. Since Pasteur's experiments on spontaneous generation were published, only thirty-six years have elapsed, and during that time remarkable results have been attained in treatment as the result of experimental pathology. The practical results already obtained affect diagnosis, prophylaxis, and treatment. The diagnosis of many parasitic diseases has now been rendered certain and easy by searching for the causal organism, and I need only instance such diseases as diphtheria, tuberculosis, malaria, anthrax, gonorrhœa, &c. The greatest of all the advances, because so wide-reaching, has been in the prophylaxis of disease, especially in the prevention of septic disease after operations, as brought about by the discoveries of Lord Lister. By these discoveries the occurrence of sepsis in wounds made through unbroken skin is prevented, and the chances of general sepsis in septic wounds are much diminished, and numerous lives are saved, not only in this way, but also by the fact that the Listerian treatment permits the performance of many life-saving operations which could not otherwise be attempted. In other cases, also, prophylaxis is of great value, as in diphtheria and in Pasteur's treatment of rabies, which may properly be grouped as a prophylactic rather than a curative treatment. Lastly, I may refer to advances in the cure of disease. In the case of diphtheria there can be no question that the antitoxin is a most potent curative agent, and that, used in the early stages, it is almost certain to cut short the disease. As regards tetanus, the evidence in the case of animals is absolutely convincing, but in patients suffering from the disease the effect is not certain, probably because we have to do with an acute illness which runs its course before the serum has had time to act. The same may also be the case with the antistreptococcic serum, although I have great doubts of its value as a curative agent. In other instances, such as plague and snake-bite, we may apparently look forward to a cure; while researches are being carried on with regard to pneumonia which may lead to valuable results; nor must I forget to mention Pasteur's system of inoculating cattle against anthrax. What are we to say about the new tuberculin? We all know how careful an observer Koch is, and the fact that he looks on it as a valuable remedy is to my mind sufficient to make it necessary to give it a careful and hopeful trial. I must say that I have always been favourably inclined to the old tuberculin, and have regarded it in relation to phthisis like iodide of potassium in relation to syphilis, and, had I been a physician, I do not think I should have abandoned it in the hurried manner in which it was thrown aside. I might enumerate many other instances of direct benefit from pathological research, such as the advances in the treatment of tuberculous diseases of bones and joints as the result of better knowledge of the nature and distribution of the disease, the treatment of appendicitis, and the investigations on peritonitis and diseases of the appendix, the more complete operations for cancer following fuller study of the mode of spread of the disease, and so on; but I have said enough to show the great importance and value of pathological research. Such results must encourage us to go on working with all our might and without ceasing, bearing in mind that many are suffering and dying every day who might be saved if only we had just a little more knowledge of the workings of the body and the processes of disease."

Dr. ALEXIS THOMSON (Edinburgh) then read a paper, illustrated by a series of slides, upon Epithelioma of the Penis.—The PRESIDENT of the section read three papers—one for Professor GOLDMAN upon Early Infection of Blood-vessels in Carcinoma and Sarcoma, one for Dr. KANTHACK on Cancer of the Testicle, and one for Dr. STILES on the Evolution of Cancer Bodies.—Professor BRYCE read a paper for Dr. PATRICK MANSON on a New Species of Filaria Sanguinis Hominis Nocturna.—Dr. IRA VAN GIESON then read an important paper on

Hæmatomyelopore.

This he described as a condition of the spinal cord following on trauma, which had to be distinguished clinically as well as pathologically from syringomyelia. Three such cases were recorded—one spontaneous, the others from trauma. The condition, which he regarded as a newly defined one, was characterised by sharp-cut canalisation of the spinal cord, usually in the posterior horns. The amount of degeneration and cavitation was out of proportion to the traces of blood effused. His experiments in injecting fluids into the cord proved that the separation of fibres always took place in a vertical direction, and usually in the grey matter. Such conditions, he thought, might be differentiated clinically from syringomyelia by the history of trauma and the rapid onset of symptoms, usually with a rapidly fatal result.

PSYCHOLOGY.

The Presidential Address in this section was delivered by Dr. R. M. BUCKE, medical superintendent of the Insane Asylum, London, Ontario, Canada, the subject being:

Mental Evolution in Man.

"Psychology," he said, "ought to be the most interesting of all the sciences, and as a matter of fact it is so, though it has been greatly discredited by the imperfection of the method by which it has until very lately been studied. That imperfection is so great that it would

Digitized by Google

hardly be an exaggeration to assert that nearly all the study and thought expended upon it down to the beginning of our own age has been fruitless and as good as wasted, except inasmuch as it has at last made clear the impassability of the route men have sought to follow—the route, namely, of introspection. As man's bodily life rests upon and grows from that of countless prehuman ancestors; as man includes in his structure the heart of the reptile, the gills of the fish, as well as the forms in outline of innumerable still lower races, so is his so-called human mind rooted in the senses and instincts of all his ancestral species; and not only so, but these senses and instincts still live in him, making up, indeed, far the larger part of his current every-day life; while his higher psychical life is merely the outgrowth and flower of them. In the growth of mind, whether that of the race or of an individual, we recognise two distinct processes: first, the very gradual evolution to, or toward, perfection of faculties that have already come into existence; and, secondly, the springing into existence (as new branches start from a growing tree) of faculties which had previously no existence. For it is clear to the least thoughtful student that no faculty (as no organ) came into mature and perfect life at once. Hearing and sight, we are told, developed by slow degrees from the sense of touch; and in the region of the intellect conceptual life was born from ages of receptual, and that from millenniums of perceptual. Let us now suppose mind growing for millions of years in the way set forth. It begins, we will say, as mere excitability; to that after a long time is added what may be called discrimination, or choice and rejection of, for instance, different kinds of food. After another long interval of almost infinitely slow advance sensation appears, and with it the capacity of pleasure and of pain; then, still later, memory; by-and-by recognition of offspring; and successively thereafter arise reason, recognition of individuals, and communication of ideas. Concurrently with these intellectual faculties certain moral functions, such as fear, surprise, jealousy, anger, affection, play, sympathy, emulation, pride, resentment, grief, hate, revenge, shame, remorse, and a sense of the ludicrous have also arisen in the nascent mind. We have reached now the mental plane of the higher animals, which is equally that of the human being at about two years of age. Then occurs in the child the mental expansion which separates man from the higher mammals—for something like a year the child mind steadily grows from the status of the latter to the status of the human mind. This year in the individual, during which it walks erect, but possesses a receptual intelligence only not having yet the power of forming either concepts or true words, represents in the race the age of *alalus homo*, the period of perhaps a hundred thousand years, during which our ancestors walked erect, but not having self-consciousness had no true language. At the average age of three years in the individual self-consciousness is born, and the infant, from the point of view of psychology, has become a human being. But we all know that after the attainment of the distinctively human faculty, self-consciousness, the child has still much to acquire both in the way of expansion of already possessed faculties and in the acquisition of new ones before it is mentally a mature man. Of the numerous faculties it still has to acquire I shall only mention here the colour sense, the sense of fragrance, the human moral nature, and the musical sense. A consideration of these four and of self-consciousness will occupy the short time allotted me to-day. Simple consciousness makes its appearance in the human infant at the age of a few days; it is absolutely universal in the human race; it dates back certainly to the earliest mammals, and probably much earlier; it is only lost in deep sleep and coma; it is present in all dreams. Shame is said to be born in the human infant at the age of fifteen months; it is a pre-human faculty, being found in the dog and in apes, and undoubtedly existed in our pre-human ancestry; it is almost universal in the race, being only absent in the lowest idiots; it is very common in dreams. Self-consciousness makes its appearance in the child at the average age of three years; it is not present in any species but the human; it is, in fact, that faculty the possession of which by an individual constitutes him a man. It is not universal in our race, being absent in all true idiots; that is, it is permanently absent in about one in each thousand human beings born into the world. In our ancestry it dates back to the first true man; a race, we are told, unclothed, walking erect, gregarious, without a true language, to a limited extent tool-using, destitute of marriage, government, or of any institution, animal, but in virtue of its highly developed receptual intelligence, king of animals, which developed self-consciousness, and by that fact became man. It is impossible to say how long ago it was when this event occurred, but it could not have been less than several hundred thousand years. This faculty is lost much more easily and frequently than is simple consciousness. We lose it in coma and also often in the delirium of fever; in certain forms of insanity, as in mania, it is often lost for weeks, even months at a time; and, lastly, it is never present in dreams. The faculty of colour sense appears in the individual at the average age of about five years. It is absent in one adult human being out of every forty-seven; it appeared in our ancestors, as Geiger has shown from linguistic palæontology, in the Aryan period, probably less than thirty thousand years ago. It is seldom present in dreams; and when it does occur, that is, when any colour is seen in a dream, it is generally that colour which for good reasons was first perceived by man—namely, red. It is thought that the sense of fragrance was acquired by the race later than the colour sense; it is also acquired later by the individual. The human moral nature belongs to a much later stage of evolution than any of the faculties so far considered. It does not make its appearance in the individual before the average age of fifteen years. It is congenitally and permanently absent in at least forty human beings out of every thousand. It would seem clear, as stated already, from a consideration of our historic ancestors, from the fact that this faculty rapidly fades out as we ascend into the past, that it cannot have existed in the race more than 10,000 years at the most. It is far more unstable in the individual than the older faculties, such as self-consciousness. It is never present in dreams. Finally, the musical sense (a faculty which is now in act of being born into the race) does not appear in the individual before the average age of about twenty years. It does not exist in more than half the members of the race. It has existed less, perhaps considerably less, than 5000 years in the race. It is never, or almost never, present in dreams, even in the case of professional musicians." Dr. Bucke here discussed the scheme of mental evolution and the atavistic theory of idiocy and insanity. He continued: "Evolution, as far as we can see, has always gone on, is going on to-day, and will always go on. Our old mental faculties are some of them fading out, others advancing toward greater perfection, and alongside of them new ones are springing up, some of which will, without doubt, be of overshadowing importance in the future. So-called telepathy and clairvoyance seem to be specimens of such nascent faculties. I place in the same class the phenomena of what is often named spiritualism. The labours of the Society for Psychical Research have made it to me plain that these phenomena, as notably in the case of W. Stainton Moses, really exist. To me these are not cases in which outside agents are acting on or through a human being, but are cases in which a given human being has faculties which are not commonly possessed. But of infinitely more importance than telepathy and so-called spiritualism, no matter what explanation we give of these, or what their future is destined to be, is the final fact to be here touched upon. This is that superimposed upon self-consciousness, as is that faculty upon simple consciousness, a third and higher form of consciousness is at present making its appearance in our race. This higher form of consciousness when it appears occurs, as it must, at the full maturity of the individual, at about the age of thirty-five, but almost always between the ages of thirty and forty. There have been occasional cases of it for the last 2000 years, and it is becoming more and more common. In fact, in all respects, as far as observed, it obeys the laws to which every nascent faculty is subject. Many more or less perfect examples of this new faculty exist in the world to-day, and it has been my privilege to know personally, and to have had the opportunity of studying, several men and women who have possessed it. In the course of a few more millenniums there should be born from the present human race a higher type of man possessing this higher consciousness. This new race, as it may well be called, would occupy, as toward us, a position such as that occupied by us toward the simple conscious *alalus homo*. The advent of this higher, better, and happier race would amply justify the long agony of its birth through the countless ages of our past. And it is the first article of my belief,

Digitized by Google

some of the grounds of which I have endeavoured to lay before you, that a race is in course of evolution."

Dr. G. H. ROHÉ (Sykesville) introduced for discussion the subject of the Etiological Relation of Pelvic Disease to Insanity, upon which many members spoke, among others Dr. R. DEWEY, Dr. D. CLARKE, Dr. J. W. BURGESS, Dr. E. N. BRUSH, Dr. URQUHART, Dr. ALEXANDER, Dr. MEEK, and Dr. SPITZKA.

OPHTHALMOLOGY.

The President of the section, Mr. EDWARD NETTLESHIP, in opening the meeting stated that owing to the large amount of work to be got through his remarks would be very brief. He felt it a great honour to have been chosen to fill the presidential chair of so important a section as that of ophthalmology. The only regret he felt in connexion with the matter was that none of his colleagues from the British Isles had been able to be present.

Antiseptics in Eye Surgery.

Dr. H. NOYES (New York) introduced the subject of antisepsis in eye surgery, and related his experience and his methods in connexion therewith. He stated that all were agreed that antisepsis was essential and he described his method as to preparation for operations as follows:—1. A patient in hospital practice was given a bath, his clothes were cleaned, his head, eyebrows, and eyelashes treated with soap and hot water and then with bichloride. The conjunctival sac was inundated with a solution of boric acid, which he considered was all that was necessary to wash away the mucous coagula. In some cases an occlusive bandage was used for twenty-four hours previously to operation. 2. Instruments were boiled for from five to ten minutes in 4 per cent. carbolic solution and covered with an antiseptic cloth. In using jointed instruments extra care was required. In practice outside the hospital the instruments are boiled before going to the patient and then immersed in alcohol immediately before using. 3. The hands of the operator were cleansed by scrubbing with soap and hot water and powdered borax, particular care being taken as to the nails, after which the hands were immersed in bichloride. 4. Dressings were sterilised by steam and kept in a tight glass jar, and the wound dressed with a bichloride solution, 1 in 3000, for twenty-four hours. He had given up washing out the anterior chamber with iodide of mercury, and questioned if the normal salt solution was not the best. Asepsis was probably better than antisepsis in these cases. In private houses he had sometimes had suppuration take place owing to defective plumbing.

Dr. RANDOLPH (Baltimore) agreed that a neutral solution was the best for the conjunctival sac, as there was much danger from the use of bichloride. He thought that plain boiled water was as good as boric acid. He did not boil the cutting instruments, but immersed them in alcohol and then in sterilised water.

Dr. BULLER (Montreal) stated that he strictly observed antisepsis. In dressing he used the dry boric acid on a moist skin. He did not wash out the anterior chamber as it caused irritation. In cases with chronic eczema he had not had suppuration since using antisepsis.

Dr. JACKSON (Philadelphia) said that bandaging of the eye immediately before operation was bad practice, and that in lacrymal obstructions the trouble could usually be located in the nose. He believed in washing out the anterior chamber.

Dr. FRYER (Kansas City) used a 1 in 6000 sublimate solution in the conjunctival sac. He did not put any dependence upon boric acid.

Dr. MITTENDORF (New York) agreed with Dr. Noyes in nearly every respect, and made an appeal for the much-abused boric acid.

Dr. RYERSON (Toronto) used boric acid and thought that the anterior chamber should not be washed out as a rule, but that some cases demanded it.

Dr. WURDEMANN (Milwaukee) allowed no one but himself or his associate to prepare the solutions and would not operate in a private house unless he had skilled attendance. He had found great results from a new anæsthetic, "holocain," which was antiseptic and had no bad effect on the cornea.

The PRESIDENT of the section gave a short account of the views of his colleagues of the British Isles, and seemed to think that the majority were in favour of asepsis.

LARYNGOLOGY AND OTOLOGY.

The President, Dr. GREVILLE MACDONALD, after a word of welcome, introduced a discussion on

Turbinotomy.

He commented on the increasing frequency of the removal of mucous membrane and portions of the turbinated bones, and in order to give room for subsequent discussion dealt with the following questions:—1. Are these operations done unnecessarily? 2. Are the symptoms relieved or cured? 3. Is harm done to the patient? The operation has been applied for relief of obstruction to respiration from hypertrophies, for the larger of which he prefers the cold snare and for the smaller the cautery. He emphasises the importance of dealing with concealed growths and cavities formed by overhanging hypertrophy of inferior turbinated bones due to structural malformation. With regard to treatment, the most satisfactory he found was paring off to provide a free passage for air and mucus by scissors or snare, and he was not in favour of extensive removals of the secreting gland of the nose, as he designated the inferior turbinated bone, which, by experiments which he cited, was proved to be the moistener of the respired air. In concluding he urged conservative treatment, and was doubtful if the removal of the least bit more than necessary was ever justifiable.

There being several papers on the subject announced to be read they were asked for before the general discussion, and Dr. PERMEWAN read for Mr. CARMALT JONES a paper on Some After-effects of Turbinotomy. This condition was reported to have been relieved in 60 per cent. of the cases, and the deafness to have been much relieved when the tinnitus stopped. Unhealthy posterior parts of turbinated bones kept up naso-pharyngeal and Eustachian catarrh, and surgical treatment offered the additional advantage of easy Eustachian treatment. Many conditions usually due to nasal obstruction or its effects on adjacent organs were reported as much relieved. No deaths or subsequent bad effects had been observed.

Dr. R. P. LINCOLN (New York), in a short paper, gave some of his own experience in turbinotomy, mentioning preliminary antiseptic preparation and the use of cocaine on cotton plugs. His treatment he divided into chemical and surgical, the former for mild grades of hypertrophy, the latter for the removal of erectile and osseous tissue by means of ignipuncture, cold wire snare, scissors, and bone-cutting forceps.

In the discussion Dr. BRYSON DELAVAN (New York) spoke on the benefits of septal treatment, and gave as his principle the gaining of a maximum of relief with a minimum of injury. He spoke against the name "spokeshave," and condemned the removal of turbinals in children, and spoke of the uncommonness of posterior enlargement of the bones.

Dr. JOHN N. MACKENZIE (Baltimore) stated that the removal of the bone or portions of it was rarely if ever done by him except for the removal of growths, and never done in children.

Mr. LENNOX BROWNE did not agree with turbinectomy and thought it was surgery in a hurry. Turbinectomy in a child he considered quite inadvisable. If there was a large turbinated bone he looked for adenoids, and in a reasonable time got improvement after proper treatment. He spoke of an association of asthma and trouble in the middle turbinated bone. He corroborated Bosworth's statement that there was no hypertrophic rhinitis without a spur, having found this to be the case in 80 per cent. of 1000 cases. He defended the name, "spokeshave," saying that we have already our chisels, mallets, saws, &c., borrowed from the carpenter's shop. He found anæmia closely associated with nasal obstruction, and agreed with the President in that he had seen many cases of dry throat following turbinectomy, and mentioned the President's careful work on the physiology of nasal moisture.

Dr. PERMEWAN, Dr. W. H. DALY, Dr. WARDEN, Dr. J. E. ROE, and Dr. R. C. MYLES also spoke.

In summing up the discussion the PRESIDENT stated that the opinion of those present seemed to be averse to Mr. Jones's radical operation for the removal of the inferior turbinated bone. He summarized the opinions expressed as

Digitized by Google

follows: 1. Complete resection of turbinated bones is almost never called for. 2. Partial removal is only occasionally required, and then of the anterior portion of the inferior turbinated.

Dr. J. H. BRYAN (Washington) then read a paper entitled the Anatomy of the Fronto-Ethmoidal and Fronto-Maxillary region, in which he dealt with the anatomy of these regions with relation to pathological conditions, based on the examination of normal and pathological frozen sections. He quoted two cases in which sinus disease of long standing was not relieved until the remote seat of the trouble in the ethmoidal cells was attacked, the sinus trouble being kept up by constant re-infection.

Dr. E. FLETCHER INGALLS (Chicago) read a paper on the Relation of Nasal Disease to Pulmonary Tuberculosis. This embraced a study of 14,953 cases studied in connexion with diseases of the nose, throat, and chest. Of these, 830 were phthisical cases in which complete examinations of the nasal organs were made. The conclusions arrived at were that nasal catarrh was much more prevalent than pulmonary tuberculosis, and that it was much less frequent in a given number of tuberculous patients than in the same number of healthy persons, demonstrating that instead of predisposing to the pulmonary tuberculosis, nasal catarrh, if it has any effect at all, appeared to prevent it.

Dr. J. N. MACKENZIE, Dr. SHURLEY, and Mr. LENNOX BROWNE also spoke.

ANATOMY AND PHYSIOLOGY.

In this Section the proceedings commenced by a discussion upon—

The Teaching of Anatomy.

The discussion was opened by Professor ALEXANDER MACALISTER (Cambridge), who remarked that the first thing to be remembered in teaching anatomy was that one was training practitioners of medicine, not professional anatomists. The difficulty in reform lay in the fact that teaching was really controlled by examiners. He then passed on to consider (1) the method of teaching, and (2) the amount to be taught. As regards the method, he emphasised the importance of dissecting and thought that every student should dissect the whole body twice, a preliminary knowledge of osteology being insisted upon. He advocated the working of students in couples and the more general use of the lens as an aid in minute dissections. The demonstrator should not dissect for the student, but should conduct catechism classes on the parts which the students were dissecting. Prepared dissections and models should be used with caution lest a diagrammatic view of the body be acquired. Lectures he regarded as the least important method of teaching anatomy, and in lecturing he preferred the practical plan rather than the morphological, although the latter was the more interesting method. He thought it regrettable that anatomical nomenclature had not been brought into line with that of biology. As regards amount, he thought that teaching must be limited, or mental dyspepsia would result. The range of knowledge was increasing, the time devoted to practical anatomy was decreasing. Teaching by schedule would not do. The most practical parts must be given most prominence. For example, a knowledge of minute muscular attachments, bony facets, &c., were of very little practical use. Two branches were underestimated: (1) the anatomy of the lymphatic glands; and (2) minute nervous connexions. Finally, he thought that an understanding was wanting between teachers and examiners in the subject as to the parts to be omitted in order that time might be best utilised.

Dr. SHEPHERD (Montreal) thought that the order of importance of the branches of anatomy was: (1) Osteology; (2) nervous system; and (3) viscera (for physicians). He also emphasised the drawbacks of teaching by specialists and the necessity for practical work. Lectures formed a skeleton and harmonised with practical work. The use of a "subject" at lectures was not of much help. Dissections could be so "good" that things looked abnormal. The application of facts to practice should be pointed out. Students were apt to remember the useless and have no sense of proportion. In his opinion histology should not be a special branch but attached to anatomy or physiology.

Dr. PRIMROSE (Toronto) condemned the practice of demonstrating minute dissections to large classes, and gave a lantern exhibition of a method of showing frozen sections to a class.

Professor MCMURRICH (Ann Arbor) advocated the use of the card system of recording students' knowledge and the result of their work. In lectures morphology should be used as explaining the "why" of things. The method of question and answer should be given prominence.

Professor WISHART (Toronto) emphasised the value of knowing anatomy "in pieces"—i.e., in order to be able to recognise parts of structures. He disapproved of the use of systematic books in the dissecting-room. Dissecting guides should be employed.

Dr. ELDER (Montreal) drew attention to the value of supplementing teaching in surface anatomy on the living subject.

Professor MICHAEL FOSTER (Cambridge) said he had not the honour to be a teacher of anatomy, and therefore spoke with hesitation, but as regards the relation of anatomy to physiology he thought one could try to teach too much of the latter, but not of the former. A medical man ought to be able to visualise the whole human frame. He thought that the teaching of anatomy should be progressive throughout a medical course. In this way it would not interfere with other subjects.

The discussion was continued by Professor MILLS (Montreal) and Dr. A. D. WALLER (London), the President of the Section.

Professor MCMURRICH presented a note on the Ganglionic Enlargement on the Posterior Interosseous Nerve of the Arm, and suggested that the nerve orginally extended to the digits. He drew attention to the presence of sensory nerve-endings in the ganglion.—Professor HUBER (Ann Arbor) described his Methods of Staining and Preparation in the Study of the Sympathetic Ganglion, and described the character of the cells and fibres and the mode of ending of the latter. He described the variations found in different animals. He said that the sympathetic neuron was always the terminal neuron in a neuronic chain.—Dr. PRIMROSE demonstrated a specimen of Uterus Masculinus, and made remarks on previous cases and its relationship to hermaphroditism.—Professor W. H. THOMPSON (Belfast) read a paper on the Degenerations resulting from Destruction of Sensory Areas of the Cortex, and showed lantern slides.—A beautiful demonstration illustrating the Histology of the Parathyroid Gland was given by Dr. WELSH (Edinburgh).

DERMATOLOGY.

The Presidential Address was delivered by Mr. MALCOLM MORRIS, surgeon to the Skin Department, St. Mary's Hospital, London, on

The Rise and Progress of Dermatology.

"A review of the progress that has been made in the knowledge of skin diseases is," said Mr. Morris, "appropriate at the present time, since what I take leave to call the centenary of the birth of scientific dermatology is not long past. In 1790 the Medical Society of London awarded the Fothergillian gold medal to Robert Willan, who had some time before submitted to it the outline of his plan for the arrangement and description of cutaneous diseases. Willan may justly be called the creator of dermatology, but he was not the first who wrote on skin disease. As our terminology bears witness, the Greeks gave a good deal of attention to the subject. Hippocrates, Celsus, Galen, Paul of Ægina, and after them the Arabians, described various affections of the integument. The first treatise professedly devoted to diseases of the skin was that of Hieronymus Mercurialis of Venice, which was published in 1572 under the title, *De Morbis Cutaneis et de Omnibus Corporis Excrementis*; the author had, however, nothing to teach beyond what he found in the ancient writers. At the beginning of the nineteenth century it could be said with perfect truth that little improvement had been made in the subject at large since the days of Avicenna. In 1808 there appeared the first volume of Willan's treatise on Cutaneous Diseases, a great work which its author did not live to complete. Ten years before he had given to the world a slender volume dealing with a particular class of lesions of the skin. It is not, however, Willans'

Digitized by Google

classification that constitutes his chief title to be regarded as the founder of dermatology. His judicious selection and accurate definition of terms, his astonishingly faithful word-pictures of the appearances of disease drawn directly from Nature, and made more vivid but scarcely more graphic by the coloured engravings with which he supplemented his descriptions, and his rational methods of treatment, were all his own. It was his teachings that transformed a confused jumble of folklore as to 'tetters,' wet and dry, and of figments of the medical imagination embodied in words of learned sound but little meaning into a science, rudimentary, indeed, but grounded on a solid foundation of observed fact. Willan's work is, therefore, rightly looked upon as the true starting point in the history of dermatology. Willan died before he could complete his work; but, fortunately, he left behind a disciple worthy to wear his mantle. This was Thomas Bateman, who had been in constant intercourse with him for many years, and who was thoroughly acquainted, not only with the teaching, but with the spirit of his 'learned preceptor.' Bateman completed Willan's unfinished 'Delineations of Cutaneous Diseases,' and published a 'Practical Synopsis of Cutaneous Diseases,' which did far more to make his master's work known than Willan's own unwieldy and incomplete book. It is hardly too much to say that without Bateman Willan might have been forgotten. Bateman, however, was not a mere expositor; he was a man of truly scientific mind, and would doubtless have added largely to knowledge had not he, too, been cut off prematurely." Mr. Morris here described the dermatological work of Anthony Todd Thomson, Erasmus Wilson, and referred to Jonathan Hutchinson. He continued: "In France a school of dermatology arose independently in the early years of the century. In 1808 Alibert published his 'Description des Maladies de la Peau observées à l'Hôpital Saint Louis,' which he followed up two years later by a 'Traité Théorique et Pratique des Maladies de la Peau,' and several other works. The most valuable part of his publications was the illustrations; his writings only added to the darkness in which the whole subject of diseases of the skin was then enshrouded. His terminology was to the last degree confusing, his classification arbitrary, his descriptions often fanciful. Yet he contributed to the advance of knowledge by directing the attention of more scientifically-minded workers to the subject. Among these was Biett, who adopted Willan's classification with some modifications, and introduced it into France. Among the leaders of the French school who followed Biett were Cazenave, Gilbert, Devergie, and Bazin, all of whom did something to advance the knowledge of skin diseases, though they were apt to let themselves be misled by a tendency to erect systems on unsound foundations. In recent years the yoke of the diatheses has been shaken off, and the labours of Hardy, Vidal, Besnier, and Brocq have placed the French school in the forefront of scientific dermatology—a position which, with such men as Darier, Thibierge, and Wickham to take the place of their seniors when they have to fall out of the ranks, it is in no danger of losing. The year 1844 marked the beginning of a new era in the study of diseases of the skin, for it witnessed the first appearance before the scientific world of Ferdinand Hebra. That remarkable man breathed a new life into the dry bones of dermatology, and set it on a path of progress which has already led to great results. Hebra applied to the investigation of skin diseases the pathological teaching of Rokitansky. His work has been carried on by Auspitz, Kaposi, and Neumann in Vienna, by Pick in Prague, Schwimmer in Budapesth, Lewin and Lassar in Berlin, Neisser in Breslau, and many others. If Willan was the creator, Hebra must be acknowledged as the greatest among the reformers of dermatology. This glory must be his in spite of the fact that his classification in its leading features had been anticipated by Rayer. Hebra, however, worked it out so fully as to make it his own; and his classification can never be superseded till an arrangement based on etiology becomes possible. The history of dermatology in America has been written by Professor J. C. White, of Harvard, and by Professor Louis A. Duhring, of Philadelphia, from whom all that can here be said on the subject is taken. Bateman's 'Synopsis' was republished at Philadelphia in 1818, a second edition being issued in 1824, and a translation of the work of Cazenave and Schedel appeared in the same city in 1829, a second edition being published in 1832. In 1845 appeared the first American work on dermatology; it was entitled 'A Synopsis of the Symptoms, Diagnosis, and Treatment of the more Common and Important Diseases of the Skin,' and its author was N. Worcester, Professor of Physical Diagnosis and General Pathology in the Medical School of Cleveland. The book is described by Duhring as being little more than a compilation from the works of the French and English dermatologists of the day. Meanwhile other signs of a growing interest in the subject were not wanting. In 1836 an Infirmary for Diseases of the Skin was opened in New York, being the first institution of the kind established in the United States, and lectures on skin diseases were delivered there and afterwards in some of the medical schools of New York between the years 1837 and 1854, by Dr. H. D. Bulkley, father of Dr. L. D. Bulkley, whose name is well known to all dermatologists. As early as 1859 Hebra's teaching was made known in America by Professor James C. White, who, two years later, gave the first course of lectures on diseases of the skin at Harvard. After the Civil War clinical lectureships on the subject were established in several important schools. In 1870 the foundation of the *American Journal of Syphilography and Dermatology* did something to promote the advancement of the knowledge of skin diseases in America, and the establishment of the American Dermatological Association in 1877 gave a powerful impulse in the same direction, which was further aided by the creation of the *Archives of Dermatology*. Yet in 1871 Professor James C. White complained that as yet America had contributed little to dermatology, and that this branch of medicine had hardly then found a place among his countrymen as an acknowledged speciality. Now this reproach has been wiped away, and American dermatology, represented by Duhring, J. C. White, Bulkley, and others, is recognised as being in the van of progress. Each of the three great schools which helped to lay the foundations of modern dermatology had certain marked characteristics. The English was essentially clinical, using classification only as a practical help in diagnosis; it observed. The French systematised, striding somewhat impatiently over facts to get at general formulas, which, though plausible on paper, too often broke down in application. The German was pathological, giving attention mainly to mechanism, and occasionally taking too little heed of the causes setting it in motion. Each school had thus the defects of its qualities, but each played an important part in the development of dermatology, and much of what was good in each still survives in the cutaneous medicine of the present day. Now, dermatology is truly international, the different schools which were formerly as separate states having become fused into one scientific commonwealth."

Mr. Morris here stated that modern research has shown that many conditions which used to be looked upon as distinct affections are really different stages in the evolution of one and the same disease. Syphilis and tuberculosis are found to produce many skin diseases formerly referred to other causes. He continued:

"Another direction in which the etiology of skin diseases has made decided progress is the recognition of the action of parasites. The idea that scabies is due to the irritation set up in the tissues by an animalcule, and ringworm by the growth on the surface of the skin of a vegetable mould, is so familiar to us that it is not easy to realise how recently the truth of these doctrines has been definitely established, and with what incredulity the discoveries were for a long time received. The sarcoptes scabiei had been seen by Avenzoar in the twelfth century, and later by Guy de Chauliac, Ambroise Paré, and others; and in the seventeenth century it was distinctly indicated as being the cause of itch by Bonomo and Cestoni."

It was here remarked that Dr. A. T. Thomson in 1850 denied that the sarcoptes scabiei was the cause of itch, and that he, Cazenave, and Chausit asserted that favus and ringworm were not due to mycoderms. Mr. Morris continued:

"Gibert, who had long been an obstinate recusant, gave in his adhesion to the parasitic doctrine in 1866, but Cazenave never recanted his heresy, and Erasmus Wilson, who, after Cazenave had passed away, stood alone in his refusal to accept the teachings of modern science on the subject, also died an unbeliever. The brilliant researches of M. Sabouraud have recently proved that the disease hitherto known as ringworm includes two, and possibly more, distinct conditions caused by different species of fungi. It has also been shown that the disease may be transmitted from animals—

Digitized by Google

particularly the horse—to human beings, a fact obviously of the greatest practical importance. During the last few years our ideas as to the action of parasites have undergone expansion. The influence of the great revolution in pathology brought about by the discoveries of Pasteur, Koch, and their disciples has been felt in the sphere of dermatology as in other departments of medicine, and we have learnt to look for the causes of many diseases in the world of the infinitely little which bacteriology has revealed to us. Already lupus, leprosy, carbuncle, glanders, sycosis, furuncle, impetigo contagiosa have been proved to be the result of the mischievous activity of specific micro-organisms. It is practically certain that syphilis has a like origin, although the microbe is not yet discovered, and similar causation is assigned to eczema, psoriasis, alopecia areata, acne, and certain forms of erythema. Quite recently Sabouraud has brought forward evidence which he thinks sufficient to prove that seborrhœa and common baldness are of the bacterial family of diseases. The administration of remedies by hypodermic injection may be mentioned as one of the most promising improvements in constitutional therapeusis; the use of mercury in this way in syphilis is becoming more and more common. The serum treatment has not yet established itself in dermatological practice, but good results from it have been reported in a few cases of syphilis, lupus, leprosy, and one or two other affections. Tuberculin as first prepared by Koch has in my own hands and in those of some other observers proved of distinct use as a preliminary to surgical treatment in lupus. The newer tuberculin gives promise of much greater usefulness, but it is too soon yet to pronounce a definite judgment as to its real efficacy. Thyroid extract has a powerful immediate effect on the integument, but my own experience does not lead me to attach much value to it as a remedy in skin disease, and that opinion is confirmed by the experience of several other dermatologists. The application of the parasitic doctrine to skin diseases has led to the introduction of a large and constantly increasing use of parasiticides; in carbolic acid, boric acid, salicylic acid, resorcin, creolin, thymol, salol, dermatol, ichthyol, chrysarobin, to mention only a few, we have powerful agents that the mid-century dermatologists knew not of. It will be long before a complete classification of diseases of the skin is possible, but this is of no great practical importance. A real stumbling-block, however, is the confusion of terminology that still exists. It would be a very real help to progress if a nomenclature at once simple, precise, and yet descriptive and international could be devised."

Dr. J. T. JACKSON (New York) reported a case of Multiple Idiopathic Pigmented Sarcoma (Kaposi). The patient was a middle-aged male from Nova Scotia, and had the lesions widely distributed over the body. They had undergone involution and much amelioration under treatment by arsenic. A histological examination had been made by Dr. Elliott, who reported that the lesions were of the type of a pigmented angio-sarcoma.

Dr. NEVINS HYDE (Chicago) spoke of a similar case at present under his care in which similar improvement had occurred under arsenical medication. He stated that the clinical course of these cases removed them from the category of sarcoma and necessitated a different description.

Dr. JAMES GALLOWAY (London) remarked on a case which he had observed for nine or ten years under the care of Dr. Stephen Mackenzie. He quite agreed with Dr. Hyde that these cases should be placed in a category distinct from sarcoma. The histological features did not correspond with those of ordinary sarcoma. The cells were degenerate in character, and more closely resembled the cells produced by chronic irritation of connective tissue.

Dr. L. D. BUCKLEY (New York) read a paper on the Non-surgical Treatment of Boils, Carbuncles, and Felons. The speaker treated the subjects under different headings, but advocated the treatment of all the minor forms of these lesions by non-operative methods. For years he had been in the habit of treating such cases by internal medication consisting mainly of sulphate of magnesia and iron, and large doses of freshly prepared sulphide of calcium, and external application of carbolic acid and ergot in the form of ointment. He recommended the renewed careful trial of treatment on these lines, being convinced that more favourable results would be obtained by this means than by the use of the knife.

(To be continued.)

Medical News.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—At the College of Medicine, Newcastle-upon-Tyne, in the first examination for the degree of Bachelor of Medicine, the following candidates have satisfied the examiners:—

OLD REGULATIONS.

Chemistry with Chemical Physics.—Leslie Herbert Walsh, M.R.C.S., L.R.C.P., L.S.A., King's College Hospital.

NEW REGULATIONS.

1. *Elementary Anatomy and Biology, Chemistry, and Physics.—First Class Honours:* Robert Simpson Hindmarch, College of Medicine, Newcastle-upon-Tyne. *Second Class Honours:* Thomas Seymour Coates, Alfred Parkin, Alfred Henry Proctor, and William Robert Davidson Daglish, College of Medicine, Newcastle-upon-Tyne.—*Pass List:* Curtis Crispin Adeniyi-Jones, Mary Evelyn De Rusett, James Herries Graham, George Mack, William Athol Murray, Henry Reah, Hermann Heinrich Ruffmann, and Frederick Riddle Scott, College of Medicine, Newcastle-upon-Tyne; and Thomas Young Simpson, Cooke's School of Anatomy.
2. *Chemistry and Physics:* Arthur Hugh Bunting, College of Medicine, Newcastle-upon-Tyne; Arthur John Spiller Brandon, St. Thomas's Hospital; William Sayce Batten, Lætitia Nora Ede, and James Farrage, College of Medicine, Newcastle-upon-Tyne; Chella Mary Hankin, London School of Medicine for Women; Marshall Hare, College of Medicine, Newcastle-upon-Tyne; Guy Hannah Kirby, Mason College, Birmingham; Ernest John Lambert Kendle, B.A., Ernest Edward Norman, College of Medicine, Newcastle-upon-Tyne; Michael Joseph Quirke, Mason College, Birmingham; Monica Lucie Mary Robertson, London School of Medicine for Women; Frank Rowland, Mason College, Birmingham; and Frank Wheler Sime, Guy's Hospital.
3. *Elementary Anatomy and Biology.*—Annie Tombleson Brunyate, London School of Medicine for Women; Henry Wallace Furnival, University College Hospital, London; James Alfred Giles and Albert Ernest Hodge, College of Medicine, Newcastle-upon-Tyne; Evan Llewellyn Jenkins, Cooke's School of Anatomy; and Archibald Cameron Ney, William Waters Stainthorpe, and Frederick George Wilson, College of Medicine, Newcastle-upon-Tyne.

LITERARY INTELLIGENCE.—The following works will soon be issued by Messrs. J. & A. Churchill: A second edition, much enlarged, of "Psilosis or 'Sprue,' its Nature and Treatment," by George Thin, M.D. St. And.; "The Means by which the Temperature of the Body is Maintained in Health and Disease," being the Croonian Lectures for 1897, by W. Hale White, M.D., F.R.C.P. Lond. (reprinted from THE LANCET); and "Economics, Anæsthetics, and Antiseptics in the Practice of Midwifery," by Haydn Brown, L.R.C.P. Edin.

THE NICHOLAS SENN PRIZE MEDAL.—The Nicholas Senn Prize Medal is a gold medal awarded to the member of the American Medical Association who presents the best essay upon some surgical subject. The competition is confined to those who at the time of entering the competition, as well as at the time of conferring the medal, are members of the association; it will be closed three months before the next annual meeting of the association, and no essays will be received after March 1st, 1898. Competitors must address their essays to Dr. J. McFadden Gaston, Atlanta, Georgia, U.S.A.

PRESENTATIONS TO MEDICAL MEN.—On the 7th inst. the members of the St. Helens Medical Society entertained to dinner, in the committee-room of the town hall, Mr. John Robertson, M.D. Edin., of St. Helens, in recognition of his appointment to the medical officership of health of Sheffield. Mr. A. Handyside, of Earlestown, president of the society, occupied the chair. The company comprised officials of the corporation, legal gentlemen, magistrates, and others. The chairman, on behalf of the society, presented Dr. Robertson with a pair of beautiful silver candlesticks and a silver bowl, remarking at the same time on Dr. Robertson's well-known work in St. Helens, as testified by standing monuments of increased sanitary efficiency and hospital improvements.—On the distribution, on the 5th inst., at the Bristol Railway Station, of certificates and medallions to the members of the Great Western Railway Class of the St. John Ambulance Association, Mr. Kisling-bury (district superintendent), in addressing the class, said the success of the previous classes would no doubt be greatly added to now that the Great Western Railway Company was formed into a centre of its own with H.R.H. Princess Christian as president. This occasion was taken advantage of by the members of the classes and some friends to present Mr. Harry F. Devis, L.R.C.P. Lond., M.R.C.S. Eng., of Bristol, with a gold watch, suitably inscribed, as a mark of appreciation of his instructive lectures on First Aid.

INTERNATIONAL VEGETARIAN CONGRESS.—During the week a congress has been held under the auspices of the Vegetarian Federal Union, at the Memorial Hall, Farringdon-street. The exhibition in the library, of the same building, of representative products of the vegetable kingdom was opened on the 13th inst. by Lady Gwendolen Herbert and has attracted many visitors. To-day (Saturday) members of the congress will visit Messrs. Carter's trial seed grounds at Mortlake and attend the Harvest Festival at, and inspection of, the Oriolet (Vegetarian) Hospital, Loughton, Essex.

WIGAN MEDICAL SOCIETY.—A meeting of this society was held in the Mining and Technical School, Wigan, on Sept. 9th, Mr. C. T. Street, President, being in the chair. Mr. W. J. Orsman, F.C.S., analyst for the county borough of Wigan, gave a lecture on, and a demonstration of, Roentgen Rays. The lecture and demonstration were highly appreciated, and a cordial vote of thanks was passed to Mr. Orsman. A paper on Empyema and its Treatment was read by Dr. W. Cunningham Milroy. A discussion followed, in which the President, Mr. Monks, Mr. Brady, Dr. White, and Mr. France took part. Dr. Milroy replied.

WE have received a circular from the Society for the Protection of Birds, of which the secretary is Mrs. F. E. Lemon, Hillcrest, Redhill, Surrey, commenting upon the wicked and wasteful destruction of birds to gratify the vanity of women. Ostrich feathers are excepted from the ban. In a letter accompanying the circular is quoted an advertisement beginning, "Sea swallows, kittiwakes; wanted, some thousands of these birds ....." This we call deplorable; traffic in birds' feathers for the purpose of ministering to the requirements of "fashion" ought to be placed under some restrictions.

DIPHTHERIA IN LONDON.—The amount of fatal diphtheria in London during the summer holiday season, when school children were free from the close association with their fellows, has varied to a certain extent. The mortality was certainly smaller during the week preceding the re-opening of the schools of the School Board for London. In the week ended July 17th, just prior to the vacation, the deaths numbered 36, or one below the decennial and corrected average for the particular week of the period 1887–96. In the next week, during which the schools broke up, but during which the pupils were under the influences of inter-association, the deaths were 42, being 6 in excess of the corrected decennial average. In the last seven days of July they numbered 41, and were just 1 in excess of the average. The first week of August yielded a total of 42, or exactly the corrected average for the corresponding week of the preceding ten years. The second week of August saw a fall to 38 deaths, a number 3 below the average; and in the succeeding and concluding week of the Board school holidays there was a further fall to 29, as compared with a corrected average of 40 deaths. In the first week of the schools reassembling, ended Aug. 28th, the fall continued, 28 deaths being registered, and the decennial average being 36. In the next and second week of return to school duties, the deaths showed a rise to 35, the corrected average being 34; but last week there was a marked fall to 25, this number being 9 below the corrected average. In the outer ring the deaths registered from diphtheria in the two weeks prior to the summer holidays were 8 and 21 respectively, the Edmonton district claiming 10 of the 29 deaths; in the four holiday weeks, they numbered 15, 10, 12 and 17; and in the three weeks since completed were 4, 4, and last week, 13, Edmonton district claiming 6 of the 21 during the period.

BOOKS, ETC., RECEIVED.

BAILLIÈRE, J. B., ET FILS, Paris.
Traité de Chirurgie Clinique et Opératoire. Par A. le Dentu et P. Delbet. Tome Cinquième. 1897.

BAILLIÈRE, TINDALL AND COX, King William-street, Strand, London.
Lawson's Tait's Perineal Operations, and an Essay on Curettage of the Uterus. By W. J. S. McKay, M.B., M.Ch., B.Sc. 1897. Price 3s. 6d.
Hand Atlas Series: Anatomical Atlas of Obstetric Diagnosis and Treatment. By O. Schaeffer, M.D. Illustrated. Vol. III. 1897. Price 12s. 6d.—Atlas and Essentials of Gynæcology. By O. Schaeffer, M.D. Illustrated Vol IV. 1897. Price 15s.—Atlas and Essentials of Bacteriology. By Professor K. B. Lehmann and Dr. Rudolf Neumann. Illustrated. Vol. V. Price 12s. 6d.

CHAPMAN AND HALL, London.
English Epigrams and Epitaphs. Selected by Aubrey Stewart. Illustrated. 1897. Price 2s.

CHURCHILL, J. & A., Great Marlborough-street, London.
The Means by which the Temperature of the Body is maintained in Health and Disease, being the Croonian Lectures, June, 1897. By W. Hale White, M.D., F.R.C.P. Reprinted from THE LANCET.
Economics, Anæsthetics, and Antiseptics in the Practice of Midwifery. By Haydn Brown, L.R.C.P., L.R.C.S. Edin.. 1897. Price 2s. 6d.

FANNIN AND CO., Grafton-street, Dublin.
Notes on the Special Hygiene (Physical and Mental) of Childhood and Youth. By Thos. M. Madden, M.D., F.R.C.S.E. 1897.

LEWIN, THOS. AND CO., Castle-street, Berners-street, London, W.
International Clinics. Edited by J. Daland, M.D., Philadelphia, and Others. Seventh Series. 1897-98. Vol. I., 1897. Price 12s. 6d. net.

LEHMANN, J. F., München.
Atlas und Grundriss der Chirurgischen Operationslehre. Von Dr. Otto Zuckerkandl. Band 16. 1897.
Atlas der Gerichtlichen Medizin. Von Professor E. Ritter von Hofmann. Band 17. 1898.

LONGMANS, GREEN AND CO., Paternoster-row, London.
Practical Domestic Hygiene. By J. L. Notter, M.A., M.D., and R. H. Firth, F.R.C.S. 1897. Price 2s. 6d.

NISBET, JAMES AND CO., Berners-street, London, W.
Health in Africa: A Medical Handbook for European Travellers and Residents, embracing a study of malarial fever as it is found in British Central Africa. By D. K. Cross. M.B., C.M., F.R.G.S. With an Introduction by Sir H. Johnston, K.C.B. Illustrated. 1897. Price 3s. 6d.

SCOTT, WALTER, Paternoster-square, London.
The New Psychology. By E. W. Scripture, Ph.D. (Leipzig). Illustrated. 1897. Price 6s.

THE F. A. DAVIS COMPANY, Philadelphia.
Annual of the Universal Medical Sciences and Analytical Index. Edited by C. E. Sajous, M.D. Paris, and others. Illustrated. Vols. I., II., III., IV., and V. 1896.

THE REBMAN PUBLISHING COMPANY, Adam-street, Strand, London.
A Pictorial Atlas of Skin Diseases and Syphilitic Affections in the Museum of the St. Louis Hospital, Paris. Parts 10 and 11. 1897. Price 10s. 6d. each.
Archives of the Roentgen Ray (formerly Archives of Skiagraphy). Edited by W. S. Hedley, M.D., and S. Rowland, M.A., M.R.C.S. Vol. II. No. 1. July, 1897. Price 4s. net.

THE SCIENTIFIC PRESS, Southampton-street, Strand, London.
The Mystery and Romance of Alchemy and Pharmacy. By C. J. S. Thompson. 1897. Price 5s.

Atlas der Syphilis. Von Dr. Martin Chotzen. Heft. 1 and 2. 1897.
Uber die Augenerkrankungen in der Frühperiode der Syphilis. Von Dr. H. Wilbrand und Dr. A. Staelin. 1897.
Praxis der Harnanalyse. Von Dr. Lassar-Cohn. 1897.

University College, Bristol: Calendar for the Session 1897-98 (J. W. Arrowsmith, Bristol, 1897); price 1s.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ANGUS, CHAS., M.B., C.M. Aberd., has been appointed Medical Superintendent to the Aberdeen Royal Infirmary, vice Lumsden, resigned.

BAILEY, JOHN GEORGE, M.B., C.M. Edin., has been appointed Senior Assistant House Surgeon to the Huddersfield Infirmary, vice T. Hill Jamieson, resigned.

DAVIES, J. E. H., L.R.C.P. Lond., M.R.C.S., has been appointed a Medical Officer by the Wrexham Rural District Council.

DUNDON, JOHN, M.D., B.Ch., has been appointed Extern Surgeon to Cork Mercy Hospital.

Digitized by Google

GILCHRIST, THOS., L.R.C.S., L.R.C.P. Irel., has been appointed Assistant Medical Officer to Sligo District Lunatic Asylum, vice G. R. Lawless.

GILES, OSWALD, L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Sleaford Rural District Council.

GORNALL, JOHN GUEST, M.A., M.B. Cantab., L.R.C.P., M.R.C.S., has been appointed Visiting Medical Officer to Winwick Asylum for Idiots under Lancashire County Asylums Board.

HARVEY, WM., F.R.C.S., has been re-appointed Medical Officer of Health by the Newton Urban District Council.

HAWTHORN, F., M.D. Durh., L.R.C.P. Lond., M.R.C.S., has been appointed a Medical Officer for the No. 4 Sanitary District of the Newcastle Union, and Public Vaccinator for the Central District.

HEATH, A., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed a House Physician to St. Bartholomew's Hospital, London.

HUGHES, Wm., M.R.C.S., has been appointed a Medical Officer for the Waenfawr Sanitary District by Carnarvon Board of Guardians.

KERSWILL, H., L.R.C.P. Lond., M.R.C.S., has been appointed a House Surgeon to the Devonshire Hospital, Buxton.

LAWLESS, G. R., F.R.C.S., L.R.C.P. Irel., has been appointed Medical Superintendent of the Armagh Lunatic Asylum.

LLOYD, EDWARD J., M.D., C.M. Aberd., M.R.C.S., has been appointed Medical Officer to the training ship *Clio*, stationed off Bangor, N. Wales.

MOBERLY, S. C. H., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the No. 2 Sanitary District of the Winslow Union, vice H. N. Pelly, resigned.

O'CONNOR, DANIEL J., M.B., B.Ch. Irel., has been appointed Extern Physician to Cork Mercy Hospital.

PETRIE, R. O., M.B., C.M. Edin., has been appointed Medical Officer to the St. Andrew's (Fife) Post Office.

ROBERTS, T., M.B., C.M. Edin., has been appointed a Medical Officer for the No. 2 Sanitary District of Carnarvon.

SLOANE, J. S., B.Sc. Lond., M.B., F.R.C.S., has been appointed an Assistant Surgeon to the Metropolitan Hospital.

SMART, W. P., L.R.C.P. Lond., M.R.C.S., has been re-appointed a Medical Officer by the Hoxne Rural District Council.

STACK, E. H. B., M.B. Camb., L.R.C.P. Lond., M.R.C.S., has been appointed a House Physician to the Bristol Infirmary.

STEELE, R. S., M.B., Ch.M. Glasg., has been appointed Medical Officer of Health by the Gnosall Rural District Council.

TEMPLETON, P., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the parish of Pirbright.

TRACY, JAMES J., M.B., B.Ch. Irel., has been appointed Intern Physician to Cork Mercy Hospital, vice M. J. Murphy, deceased.

TWIGG, F. G., L.S.A., has been re-appointed Medical Officer for the Mexborough Sanitary District of the Doncaster Union.

WADDELOW, J. J., F.R.C.S. Eng., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health by the Whittlesey Rural District Council.

WARING, H. J., B.Sc. Lond., M.B., F.R.C.S., has been appointed Surgeon to the Metropolitan Hospital, and also Surgeon to the Department for Diseases of the Throat at that Hospital.

WRIGHT, W. H., L.R.C.P. Irel., M.R.C.S., has been re-appointed Medical Officer by the Alvaston District Council.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ABERDEEN CITY HOSPITAL.—Resident Physician at the City (Infectious Diseases) Hospital. Salary £50 per annum, with board and residence at the hospital. Applications to the Town Clerk, Town House, Aberdeen.

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon. Salary £150 per annum (with an allowance of £30 per annum for cab hire), and furnished rooms, fire, lights, and attendance.

GENERAL HOSPITAL, Nottingham.—Assistant House Surgeon for twelve months. Salary £50, with board, lodging, and washing in the hospital. Also Assistant House Physician for twelve months. Salary £50, with board, lodging, and washing in the hospital.

GENERAL INFIRMARY, Northampton.—Resident Dresser for six months. Board, lodging, and washing provided.

GUEST HOSPITAL, Dudley.—Resident Assistant House Surgeon for six months. Board, lodging, and washing in the hospital provided.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident Medical Officer, unmarried. Salary £200 per annum, with board and residence. Also Resident House Physicians.

KIDDERMINSTER INFIRMARY AND CHILDREN'S HOSPITAL.—House Surgeon, unmarried. Salary £140, increasing by £10 per annum to £170, with rooms in the infirmary and attendance.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W.—Assistant Resident Medical Officer for six months. Residence, washing, and board provided, and an honorarium given at the termination of the appointment.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Shoreditch, N.E.—Junior House Physician for six months. Salary £15 for that period, with board and residence.

OLDHAM INFIRMARY.—Junior House Surgeon. Salary £50 per annum, with board and residence.

ROYAL CORNWALL INFIRMARY, Truro.—House Surgeon, unmarried. Salary, first year, £120, increasing by £10 a year to £150, with furnished apartments, fire, lights, and attendance.

ROYAL SOUTHERN HOSPITAL, Liverpool.—Junior House Surgeon. Salary 60 guineas per annum, with board, &c.

STOCKTON AND THORNABY HOSPITAL.—House Surgeon, non-resident. Salary £200 per annum.

SWANSEA GENERAL HOSPITAL.—House Physician for one year. Salary £50 per annum, with board, apartments, laundress, and attendance.

WEST HAM HOSPITAL, Stratford, E.—Junior House Surgeon for one year. Salary £35 per annum, with board, residence, &c.

Births, Marriages, and Deaths.

BIRTHS.

McDOWALL.—On Sept. 12th, at Menston, near Leeds, the wife of J. G. McDowall, M.D., of a daughter.

REID.—On Sept. 6th, at Oakley, Kirkcudbright, the wife of W. S. S. Reid, M.B., of a son.

MARRIAGES.

BARNES—HOLLIST.—On Aug. 26th, at St. Peter's Church, Lodsworth, by Rev. C. S. Chilver, Vicar of the Parish, assisted by Rev. L. Brooke-Barnett, Curate of Compton, Herbert Cooper Barnes, M.R.C.S., L.R.C.P. Lond., of Petworth, Sussex, youngest son of James Barnes, Esq., of Tiverton, N. Devon, to Lilian Capron, younger daughter of Lieutenant-Colonel E. O. Hollist, of Lodsworth House.

BEDFORD—FOORD.—On Sept. 8th, at SS. Philip and James, Cheltenham, Surgeon-Major W. J. Guthrie Bedford, second son of the late E. S. P. Bedford, F.R.C.S., to Mabel Stanley, fourth daughter of Edward Bromley Foord, M.C.S. (retired).

BELL—MACKAY.—On Sept. 8th, at Elgin, William Bruce Bell, M.B. Edin., Higher Broughton, Manchester, to Helen Louise, youngest daughter of H. M. S. Mackay, banker, Elgin.

BLACKLER—ADAMS.—On Sept. 8th, at St. Mary the Virgin, Primrose-hill, Henry John Blackler, M.B., of Redhill, to Sybil Mary, daughter of W. Bridges Adams, M.R.C.S., &c., of Belsize-park.

DOBBYN—TAUNTON.—On Sept. 9th, at Holy Trinity Church, Birchfield, Michael Gilbert Dobbyn, L.R.C.P., L.R.C.S. Irel., of Bishopston, Bristol, to Frances Elizabeth, younger daughter of Mr. R. H. Taunton, of Brook Vale, Witton, Birmingham.

GOODCHILD—BRITTAIN.—On Sept. 8th, at St. Barnabas's Church, Bartholomew-road, N., John Goodchild, M.R.C.S., L.R.C.P., of 9, Highgate-road, N., to Alice Emma (Dollie), second daughter of John Brittain, of Hilldrop-road, Camden-road, N.

HAYDON—CHRISTIE.—On Sept. 9th, at St. Stephen's, Avenue-road, London, Thomas Horatio Haydon, B.A., M.B., of Marlborough, to Minnie, second daughter of the late John Christie, Park-crescent, Stirling, N.B.

MAW—MCNAMEE.—On Sept. 15th, at the Parish Church, Kensington, Henry Trentham Maw, M.D., second son of Charles Maw, of Nutfield, Surrey, to Elizabeth, youngest daughter of the late Peter McNamee, Sherwood Foresters, of Dundalk, Ireland.

STEPHENS—BUTLER.—On Sept. 9th, at St. Stephen's Church, Kirkstall, Leeds, Cecil Edward Stephens, M.B. Edin., younger son of the late Dr. Stephens, of Doddington, to Enid Rose Harding, eldest daughter of A. Edmund Butler, J.P., of Kepstorn, Kirkstall.

SYDENHAM—TURNER.—On Sept. 3rd, at Holy Trinity, Cheltenham, by the Rev. Percy Waller, Fredk. W. Sydenham, M.B., C.M. Edin., D.S.Sc. Vict., of Walsall, to Nellie King Turner, of Cheltenham.

THORPE—RODHAM.—On Sept 10th, at Yateley, Hants, by the Rev. R. Oscar T. Thorpe, M.A., Rector of Anstey, Herts, father of the bridegroom, assisted by the Rev. C. D. Stooks, M.A., Vicar of the Parish, Surgeon V. Gunson Thorpe, R.N., M.R.C.S., to Maude, daughter of the late Fleet-paymaster C. R. Rodham, R.N.

DEATHS.

RYE.—On Sept. 1st, at his residence, Westbury, Caterham Valley, Surrey, Arthur Brisley Rye, F.R.C.S., aged 85.

STEPHENS.—On Sept. 11th, in consequence of a bicycle accident at Preston, Richard John Stephens, M.R.C.S. Eng., L.S.A. Lond., Assistant Medical Officer, County Asylum, Whittingham, Lancashire, in his 34th year.

TANNER.—On Sept. 14th, in London, Mark Batt Tanner, M.D., formerly of Brighton, in his 65th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1897, which was completed with the issue of June 26th, was given in THE LANCET of July 3rd. It is intended, in future, to include the Index and Title-page for each past half-yearly volume in the first number of the succeeding volume, as in the present case, instead of in the last number of the volume itself, as heretofore.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1897 are now ready. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

A QUESTION OF ETIQUETTE.

WE have had a statement submitted to us from one of the interested parties concerning the seeing of a patient, B, under the care of one practitioner, C, by another practitioner, D, in C's absence, at the request of B and her husband, A. So far as we can judge from the statement—a one-sided one, in that it emanates from one of the practitioners only—D acted with absolute courtesy and professional rectitude, and is in no way to blame.

Notifications.—We regret to be quite unable to give a definite answer at so short a notice and on such scanty information. If a detailed account of the matters in dispute is sent to us, with full names and dates (of course, in confidence), we will endeavour to assist our correspondent who, in the meantime, is advised not to go to law without being sure of his ground and backed by a solicitor's opinion.

TREATMENT OF EPISTAXIS.

DR. HAGKDORN, writing in a recent number of the *Zeitschrift für Praktische Aerzte* on epistaxis, assures his readers that if the patient is merely made to hold his head up high so that the alæ nasi are pressed against the septum 90 per cent. of the cases which are due to hæmorrhage from the anterior cartilaginous portion of the septum will cease. A speculum should then be very cautiously introduced and an examination made in order to find out whether any ulcer or varicose vein exists. If so it should be touched with the galvano-cautery or trichloracetic acid after cocaine has been applied. The eschar which this produces must not be disturbed, great care being taken in this respect whenever the nose is blown; it will fall off in eight or ten days. If the hæmorrhage comes from the inferior or middle turbinated bone plugging must be resorted to, which is best effected through the speculum by means of small tufts of aseptic wool, care being taken to see that no blood is escaping by the pharynx. After the plug has remained twelve hours it should be removed, and the spot from which the bleeding proceeded cauterised as in the other class of cases. Where the hæmorrhage comes from the posterior parts of the nostrils the naso-pharyngeal space must also be plugged, and this is best accomplished by the introduction of tampons of aseptic wool by means of well-curved polypus or laryngeal forceps, guided, of course, by the finger. This plug must on no account be allowed to remain more than about twelve hours for fear of erysipelas, gangrene, septicæmia, or purulent otitis supervening; if necessary a fresh plug may be introduced. Perchloride of iron wool is, in Dr. Hagedorn's opinion, distinctly dangerous. The most troublesome cases of all are those in which there is general parenchymatous oozing in subjects of hæmorrhagic diathesis; here repeated plugging, absolute rest, and hydrastis Canadensis should be employed. Sprays are not to be recommended.

M.B., C.M. Glasgow.—An M.D. need not qualify his degree by adding his University, but we always advise him to do so. For the rest, we do not quite understand what it is our correspondent complains of.

EXAMINATION GEMS.

DR. W. D. HAMAKER, a member of the State Board of Medical Examiners, has communicated to the current number of *The Pennsylvania Medical Journal* an amusing little note on the blunders that have been made by students who have appeared before him in the course of his official duties. Some of the medical errors which he chronicles are decidedly astounding as well as amusing, for it is difficult to understand how a candidate capable of giving such answers as those that now follow could ever have conceived that he had commenced to study his subject:—

> "'Hydrogen gass is degenerated from the urea'; 'Cantharides is derived from the root of the plant'; 'Pix liquida is from the Pinus Sommferous group'; 'Cantharides is derived from the destructive distillation of the Spanish fly'; 'The malar bone articulates with the occipital bone'; 'Picrotoxin is an alkaloid of senna and rhubarb'; and 'Spartein and eserine are alkaloids of somnis papaverum.' One hopeful candidate said that 'Spartein was derived from Sparta,' and another that it 'was derived from Spartus.' Another said 'that vinegar was an antidote for mineral acid poisons,' and another stated that 'An infusion of Spanish fly was one of the official preparations.' Another gave us the information that 'the uriniferous tubules secrete the seminal fluid.' Another said that 'belladonna locks up all of the secretions except the urine and feces.' Another stated, without additional matter of any kind, that 'the differential diagnosis between epilepsy and hysteria is that in epilepsy they fall on the stove and burn themselves and in hysteria they don't.' Turning to obstetrics we found one man who, in rigid os, 'would decapitate or perform craniotomy or would put on the forceps and deliver at once.' Another in performing version 'would put his finger in the child's mouth and bring the chin under the os pubis and hold his hand over the mouth to prevent the liquor amnia from choking it.' Another stated 'that the endoxardium is a mucous membrane which weighs 2oz., and is separated from the pleura by the pericardium.' Another stated 'that the function of the optic nerve is to contract the pupil and move the eyeball.' A new diagnostic symptom was offered by the gentleman who stated in a written paper that 'in cerebral hæmorrhage the patient may vomit the cerebro-spinal fluid.'"

Dr. Hamaker also gives examples of instances of want of common education, advancing them as arguments that a higher level of preliminary education should clearly be required from the American medical student.

> One applicant spelled tongue, "tong"; another spelled salts, "saults"; another spelled broom, "brougham"; another spelled fly, "fley," and flies, "flyes"; one young lady spelled sugar, "shugar"; another applicant spelled Spain, "Spane"; fir-tree was spelled "fur-tree"; another spelled pulse, "pultz"; and sore was spelled "soar"; and another spelled pus "puss."

QUEERNESS IN A TALE.

A "QUEER STORY" in *Truth* is not to be taken seriously, but even in ephemeral literature there are limits beyond which queerness should not be pushed, and in the *Truth* feuilleton of Sept. 2nd that limit was exceeded. Mr. Hall Caine's specimen of the nursing sisterhood has a few redeeming points, but *Truth's* specimen, Nurse Denison—although Dr. Pillington describes her as "the most attentive nurse in London ..... and one of the few whom I can really trust in very critical cases"—can only be pronounced a hopelessly weak-minded, vicious simpleton, without any redeeming points whatever. "Dr. Pillington had a very 'smart' practice indeed. It was an almost exclusively society practice, only touching here and there one who was outside the sacred pale. He was eminently qualified for this class of work, being distinguished by exceptional polish and refinement, and having the air of a thoroughly well-bred man, which, indeed, he was." But, unfortunately, this paragon was also a confirmed gambler, and had been "mad enough to forge another man's signature to a promissory note." One Scaasi, "a blood-sucking usurer," finds this out, and in the ordinary course of his business puts the screw on Dr. Pillington "to make some intentional mistake in his treatment" of a certain Duke, whose spendthrift son and heir in consideration of an immediate advance of £20,000, had executed a post-obit bond for £100,000 in favour of the said blood-sucker. So far the lines of the humble penny dreadful have not been notably departed from, but *noblesse oblige* and queerness has been dragged in *coûte que coûte*. The paragon recoils with horror from the dastardly scheme. He is far too well-bred to commit such a base crime himself, so lets Nurse Denison know that he would like her to carry out the usurer's order. Nurse Denison, who has been winning the Duke's gratitude by attending on him "with a skill, a gentleness, a consideration that were beyond all praise," has not the slightest objection to oblige, and his Grace incontinently receives "a double dose of his sedative medicine," which, *mirabile dictu*, at once proves fatal. The poisoner, it should be noted, was not actuated by any "sordid or selfish motive." Far from it. "She was madly in love with Dr. Pillington, and she did what she did solely for his sake."

L.F.P. & S. will find in our Students' Number (published this year on Aug. 21st, but as a rule published in the first week in September) full information on the subject. All the fees for the different courses at the different London hospitals are there given in detail.

Vienna.—We have inquired.

STERNUTATORIES AS A SUBSTITUTE FOR THE FORCEPS IN LABOUR.

To the Editors of THE LANCET.

SIRS,—On reading Dr. Lauder Brunton's interesting book ("Lectures on the Action of Medicines") I was surprised, and not a little astonished, to see the statement that "sternutatories are sometimes employed in country practice as substitutes for the forceps in labour." Now I do not for a moment suppose that anything in the way of a sneer was meant in this opinion, or that the forceps are not as intelligently used by the country practitioner as by his *confrère* in town. I have certainly heard of sternutatories used as an aid to labour, but mostly, I think, by old women, and in the form of snuff, but certainly not by country medical men, specially as a substitute (or in the way of saving labour) for the forceps. However pleasant sneezing may be, and no doubt a good sneeze is not to be despised, yet very few intelligent accoucheurs, either in town or country practice, would risk allowing the fœtus to be expelled in this perfunctory and, let me add, unscientific manner, and thus running the untold risks of perineal rupture and death from hæmorrhage to both mother and child. So far from trusting to such unsatisfactory substitutes, and in this category I do not exclude ergot, the country practitioner has been blamed with using instruments too freely, and I am sure very few men, especially those with anything like a wide experience, would for a moment compare these more or less unreliable remedies to the scientific adaptability of a good pair of forceps. No; with the forceps we can guide, control, and complete the labour when we choose, and thus perhaps, not only save a child's life, but the patient a certain amount of prolonged and unnecessary suffering. A practitioner who knows anything about forceps delivery will not for one moment consider the trouble of applying the instrument, but, like every other scientific operator, rather take a positive pleasure in the assured and apparent efficiency of his art. It is not always given to the country practitioner to step forward on the platform of recognised merit, but I think in matters obstetric he was not born yesterday (if I may be allowed the vulgarism) nor necessarily in the country.

I am, Sirs, yours faithfully,

Rothwell, Northamptonshire. JAMES MORE.

Inquisitive should consult his medical attendant. The case is one in which special assistance might be necessary, and his medical attendant could tell him whom to consult. We do not give medical advice.

MORE QUACKERY.

A CORRESPONDENT sends us the following handbill, which we reproduce *verbatim et literatim*. In our opinion the Christian young men of Walsall might find some better use for their private rooms than to lend them to ignoramuses of this kind. At what date was Sir Andrew Clark ever "Sir Morrell McKenzie"? Some day possibly some patients, "after having been fit with an appliance," will discover that they have been swindled, but until this sort of thing is made illegal it will always flourish. We observe that "spinal weakness" is "a speciality." Personally we should have thought the weakness existed in another part of the organism, but pigeons for plucking will always be found by those who look for them.

A WORD TO SUFFERING WOMEN.

NURSE SLATER

will visit WALSALL for four weeks, commencing Wednesday next. Hours 2.30 to 6 p.m.

ADVICE FREE

At the Private Rooms of the Y.M.C.A., Freer St., WALSALL.

Mrs. Slater's experience in all Inward Complaints of Women is unequalled. Her

PROLAPSUS UTERI BELT

is Specially Adapted for the Prevention and Cure of the Falling of the Womb, without wearing any Inward Instrument whatever.

Sir Andrew Clark, late Sir Morrell McKenzie, Dr. Stephen McKenzie, &c., &c., can with confidence recommend her Appliances to the suffering.

TUESDAYS ONLY.

Many who have suffered from this painful complaint and have tried instruments of every kind and derived no benefit, have proved the Belt a great blessing.

Those who have only been able to do their work in pain and suffering have soon found relief, and thousands who had given up hope of ever being well again are now going about as well as ever they were in their lives.

Rings, Cradles, and every description of Inward Instruments are now almost universally condemned by the medical profession—because such things are the source of tumours to an alarming extent.

A poor woman from Wolverhampton, who earned her living at the washtub, and who had worn a Belt for 2 years, wrote: "Before wearing your appliance I never had a day's comfort. The bearing down Pains, and pains in my back, were so bad that I scarcely knew what to do. Now I am like another woman. I can do my work, and it is a pleasure to do it."

It is of great importance that any wishing to see her should do so at once as she cannot stay but a few weeks, and she always prefers to see each patient after they have been fit with an appliance in order to judge how they are progressing.

The great difficulty is to persuade sufferers that they have nothing to be afraid of. One who came said, "Why, Mrs. Slater, I was afraid of coming, but had I known who I was coming to, I shouldn't have had any need. It's more like seeing a friend than anyone else."

THE COMPRESS BELT

For Stoutness, is invaluable to all stout people. It not only reduces the measurement, but it causes them to breath much easier and freer, and also causes walking to be a pleasure. ALL ADVICE FREE.

SPINAL WEAKNESS a Speciality. Don't delay your visit.

TUESDAYS ONLY.

Mr. Slater will attend for Men at the same Address

FROM 5 0 P.M. TO 6.0 P.M.

If you are ruptured, see him. If he cannot hold your rupture he will tell you so. No person need suffer from an ill-adapted or bad-fitting Truss. All children may be cured permanently if brought in time. Come soon. No charge for advice. Note address and hours of attendance—

Private Rooms of the Y.M.C.A., Freer-street, Walsall.
Hours 5 to 6.

Adipose Tissue.—A medical man writing under this pseudonym would feel much obliged to anyone who could give him full particulars of Mr. Banting's system of dieting for obesity, or of any other system which would have a similar effect.

A Correspondent in Whitehaven.—"A Code of Medical Ethics," by Jukes de Styrap, M.K.Q.C.P., &c. H. K. Lewis, Gower-street, London, W

"THE DISPOSAL OF IMPORTED BAD EGGS."

DR. COLLINGBRIDGE (the medical officer of health of the Port of London), in reference to the annotation in THE LANCET of Sept. 11th under the above heading, refers us to an article in the *City Press*, which says that the cargo of eggs was not condemned at Greenwich and by the Port Sanitary Authorities, and that this fact relieved them of the responsibility of disposing of the offensive cargo in an efficient manner. If the eggs had been condemned by the Port Sanitary Authorities they would have been disposed of in a more approved way. But we still do not see why the eggs were not condemned at Gravesend, in which case we do not doubt they would have been so disposed of as at any rate not to have led to a nuisance and offence to the neighbourhood, as was the case when they were destroyed at Limehouse.

Lungo.—What our correspondent proposes to do is always open to the accusation of unprofessional conduct. He must be a law to himself, for he alone knows how far his negotiations with a brother practitioner have given him an insight into matters which would otherwise have remained private for him.

J. R. T.—If our correspondent's friend did not raise the point in his agreement and has received his salary weekly we think he must accept a week's notice.

"FONETIK AND RASHONAL MEDIKAL FRAZEOLOGY."

A FREQUENT correspondent sends us the following *résumé* of a paper read by Dr. George M. Gould, of Philadelphia, the author of the magnificent medical dictionary, in which the cause of a "simpler" spelling of medical terms is amusingly urged:—

"Specifically, the microscopic modifications I urge are," says Dr. Gould:—

"1. Abolish in English words archaic, unnecessary, bothersome 'æ' and 'œ,' supplanting them by 'e.'

"2. Cease adding tautologic 'al' to adjectives having already one adjectival suffix 'ic'—already done in thousands of words; finish the job. As, prosaic for prosaical.

"3. Drop the useless hyphen in words whose parts are derived from classic languages. In ten thousand words you have already done so; finish with the rest. Retain the hyphen in such compound terms as express a single idea by two semi-fused English words, especially when both are nouns; as, antitoxin (not anti-toxin), culdesac, postmortem, ventrofixation, &c. Keep the hyphen, because necessary to avoid confusion and doubt, in curette-spoon, heart-murmur, skin-disease, sleeping-sickness, &c.

"4. Drop useless 'te' from curette, brunette, fourchette, etiquette, cigarette, &c. You have already lopped it off from cutlet, doublet, quartet, quintet, sextet, septet, racket, minuet, fillet, corset, stylet, tourniquet, bouquet, &c.; finish the job. Cut off useless 'me' from many words, writing program, gram, centigram, &c., just as already we do telegram, anagram, diagram, epigram; let us make an end of it.

"5. Use figures instead of spelling out numbers, at least above ten.

'6. Anglicise foreign terms when a goodly proportion of your readers will not understand them in the originals. Use italics as little as possible; use as few foreign words and terms as possible, because the vast majority of your audience cannot understand them (even if you do); and because there is a deal of silly conceit in airing exotics of speech.

"7. As to chemic terms, accept recommendations of the American Association for Advancement of Science, which, after years of dispassionate investigation, advised dropping final 'e' in bromide, iodide, bromine, iodine, atropine, quinine, &c. Say phenol for carbolic acid, glycerol instead of glycerine, &c.

"8. Abolish diæreses and accents. They cannot teach pronunciation: they are useless luggage. Let us write oophorectomy, cooperation, ptomain, leukomain, &c, without the diæresis. When a foreign word is Anglicised let us do it completely, and not drag into our domain exotics of foreign habit, leaving it, e.g., neither English nor French. To poets leave the acute, grave, and circumflex accents, foreign to the spirit of our tongue.

"Finally, consider the source and secret reasons for opposition to the foregoing. Ignorance—colossal, imperturbable, impertinent ignorance characterises much of it. ..... Not only can there be no valid objection to such simplified spelling, but there are many good reasons for its use. We must get out of this thraldom of foolish, difficult, and heterogeneous spelling."

Busy Practitioner will find no convenient books embracing both subjects. The names of the books answering his purpose will be found on p. 442 of the Student's Number of THE LANCET, Aug. 21st, 1897.

PROPOSED CASTRATION OF IMBECILES AND CRIMINALS.

THE *Philadelphia Medical and Surgical Reporter* states that a Bill has been introduced into the Michigan Legislature providing for the castration of all inmates of the Home of the Feeble-minded and Epileptic before their discharge, of all persons convicted of felony for the third time, and of those convicted of rape.

SOFT RUBBER SCREW DRAINAGE TUBE.

To the Editors of THE LANCET.

SIRS,—Cases occasionally occur where deeply-seated abscesses have to be drained through a sinuous track through which it is impossible to pass an ordinary drainage tube and dangerous to use long sinus forceps or tube introducers. In such cases as small localised empyemata, localised peritonitis, drainage after ruptured extra-uterine gestation, abscess situated amongst the bowels with a sinuous sinus, I have found the following device invaluable. An ordinary drainage tube is neatly cut with sharp scissors into the form of a right-handed screw at the end. It is put into the sinus, and when its course is arrested it is turned round to the right. The end easily finds its way in the right direction and the rest of the tube follows without any damage to the surrounding parts, and with a facility which is often surprising.

I am, Sirs, yours faithfully,

THOS. CARWARDINE.

*** The device is new to us, and strikes us as very ingenious.—ED. L.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (20th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. A Clinical Lecture

ON

HYSTERICAL MUTISM AND OTHER FUNCTIONAL SPEECH DEFECTS.

Delivered at University College Hospital on July 12th, 1897,

BY H. CHARLTON BASTIAN, M.D.,
F.R.C.P. LOND., F.R.S.,
PHYSICIAN TO THE HOSPITAL AND TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

GENTLEMEN,—In my recently delivered Lumleian Lectures I dealt mainly with defects of speech referable to lesions in one or other of the four cortical word-centres, but the limited time at my disposal compelled me to omit one important section of this subject—namely, the consideration of the defects due to functional disabilities in the glosso-kinæsthetic word-centre. This portion of the subject, therefore, I propose to consider to-day.

Aphasia occurs not unfrequently in association with various sets of conditions as a temporary disability, and sometimes with a marked tendency to recurrence, where the brief duration and the complete recovery make it improbable that it can have been due to any gross lesion.

What the proximate causative conditions have been in these different sets of cases it is often impossible definitely to say. Instead of softenings of brain tissue or hæmorrhages, abscesses, new growths, or traumatisms of the brain as causes of loss of speech, we can only, in order to account for the defects of which we are now about to speak, appeal to ischæmia (from irritative congestion, temporary thromboses, minute embolisms, or spasms of vessels) affecting the posterior part of the left third or of the second and third frontal convolutions; to "inhibition" variously brought about; or to other little-understood causes leading to degradation of function in the same parts. Whatever the precise cause of the disability happens to be, this may—as with functional paralysis of limbs—persist for variable periods (hours, days, weeks, months, or even two or more years), and yet permit ultimately of a perfect restoration of function more or less rapidly brought about.

In these cases we have to suppose that from one or other of the causes above referred to the molecular mobility of the glosso-kinæsthetic centre is so reduced that it is unable to send down to the bulbar speech-centres incitations strong enough to call them into activity.

The principal causative or associated conditions may now be referred to in succession.

(*a*) *Irritative congestion or thrombosis following upon excessive literary work or worry, or as a result of exposure to cold.*—Trousseau recorded several interesting cases of this type,[1] and many others have since been published by subsequent writers. The case of his colleague, Professor Rostan, which Trousseau quotes, may be here reproduced as a typical instance of the kind of defect with which we are now concerned.

CASE 1.—"Rostan had been confined to his bed for a few days in the country in consequence of an injury to one of his legs, and, being alone there, he read all day and thus fatigued his brain. He was engaged one day reading Lamartine's 'Literary Conversations,' when he suddenly noticed that he did not clearly understand what he was reading. He paused for a short time, but on beginning again he made the same remark. Alarmed by this, he tried to call for help, but to his extreme surprise he was unable to utter a word. Believing himself to be struck with apoplexy, he then executed various complex movements with both his hands and with his uninjured leg, and thus found that he was not paralysed. He then rang the bell, and when a servant came into the room Rostan could not speak a single word, and yet he could move his tongue in every possible direction, and was perfectly aware of this singular discrepancy between the facility with which his vocal organs were moved and his inability to express his thoughts in words. He made signs that he wished to write, but on pen and ink being brought to him he was as incapable of expressing his thoughts in writing as in speaking. On a medical man arriving two or three hours afterwards Rostan pulled up his shirt-sleeve, and, pointing to the bend of his arm, clearly intimated that he wished to be bled. No sooner was the bleeding over than he was able to say a few words, although incoherently and imperfectly. Still some of these words clearly expressed an idea, whilst others seemed to have no relation to the principal idea. By degrees the veil was removed, he had a greater command of words to express his ideas, which also became more numerous, and at the end of twelve hours recovery was complete."

Long before anything definite was known about aphasia a very similar case was recorded by Scoresby Jackson[2] of Pennsylvania. The case is quoted by Bateman,[3] from whose work I take it.

CASE 2.—"The Rev. Mr. ——, aged forty-eight years, endowed with intellectual powers of a high order, of a sanguine temperament, with latterly a strong tendency to obesity, having exposed himself to the influence of the night air, received a check to the cutaneous perspiration. The next morning he awoke with a headache, and when a friend went into his room to inquire after his health he was surprised to find Mr. —— could not answer his questions.

"Dr. Jackson having been summoned, found the patient in full possession of his senses, but incapable of uttering a word; the tongue was not paralysed, but could be moved in every direction; all questions were perfectly comprehended and answered by signs, and it could be plainly seen by the smile on his countenance, after many ineffectual attempts to express his ideas, that he was himself surprised and somewhat amused at his peculiar situation. The face was flushed, the pulse full and somewhat slow, and to the inquiries if he felt pain in the head he pointed to his forehead as its seat. When furnished with pen and paper he attempted to convey his meaning, but he could not recall words, and only wrote an unintelligible phrase, 'Didoes doe the doe.' Forty ounces of blood were drawn from the arm, and before the operation was completed speech was restored, though a difficulty continued as to the names of things, which could not be recalled. The loss of speech appearing to recur in fifteen minutes, ten ounces more blood were abstracted, and sinapisms applied to the arms and thighs alternately. These means were speedily effectual, and no further return of the affection took place."

In each of these cases we see that the aphasia was associated with agraphia; and that the functional disability was not limited to the third frontal gyrus seems further shown by the fact that during recovery these patients also showed some degree of verbal amnesia or paraphasia.

(*b*) *Minute embolisms.*—Nothnagel[4] has called attention to cases of this kind in which patients suffering from valvular heart disease were suddenly attacked with aphasia, unattended by other symptoms, the loss of speech disappearing in the course of one or two days. Hammond[5] also mentions the case of a woman who, after repeated attacks of acute rheumatism, with marked aortic insufficiency, was seized with headache and vertigo whilst conversing with a friend, and whose speech was abruptly cut short. She was rendered completely aphasic, but recovered within forty-eight hours.

(*c*) *Spasm of vessels.*—Sometimes the temporary ischæmia which leads to aphasia is due neither to irritative congestion, temporary thrombosis, nor minute embolism, but seems to be occasioned rather by spasms of vessels. A good instance of this supposed mechanism leading to "recurring attacks of transient aphasia and right hemiplegia" has been recorded by E. O. Daly,[6] of which the following is an abstract:—

CASE 3.—A man, aged sixty-eight years, was suddenly seized, on March 11th, at 6 A.M., with aphasia and right hemiplegia. The attack lasted about five minutes and passed off as rapidly as it came on. He had suffered occasionally for years from gout, most frequently affecting his bladder. The first sound of his heart was found to be feeble; his arteries were thickened, and his urine was pale, with a well-marked trace of albumin, and a specific gravity of 1010. His temperature was normal and his pulse 80 per minute.

On March 13th he had two attacks of a precisely similar kind to the first, each lasting about half an hour.

On March 14th there were ten attacks, the shortest lasting about ten minutes, the longest almost an hour.

On March 15th there was one attack of ten minutes' duration, and three in succession with about a ten minutes' interval between, each extending over three hours.

After March 15th he remained quite free from an attack of any kind. The treatment consisted of perfect rest, a few grains of calomel, and a mixture containing small doses of iodide of potassium and citrate of lithia.

Dr. Daly says: "I saw this gentleman during several of these attacks. They came on perfectly suddenly without any premonitory symptoms, and passed off as rapidly. He would suddenly say, 'I am all right again.' There was never any kind of convulsion. ..... When asked to put out his tongue he did so at once, and also closed his eyes and performed intelligently all actions asked of him. The aphasia was not complete, but the words he had at his command were limited and frequently misapplied; and in some of the attacks he was quite unintelligible. The hemiplegia was also partial, more marked in the arm than in the leg. He could move the right hand to a limited extent, and was able to grasp my hand feebly. There was also slight anæsthesia of the right side. ..... The attacks in every instance ended abruptly, the speech becoming instantaneously perfect. The power in his right side returned almost as rapidly, but after the long attacks a few minutes elapsed after the return of speech before he could use his arm and leg perfectly."

This is certainly a remarkable case, and it seems more explicable on the supposition that the recurring attacks were

due to recurring spasms of vessels, perhaps under the influence of gouty and uræmic poisons in the blood than in any other way. Brissaud refers to another case of recurrent aphasia with right hemiplegia which showed itself in a woman suffering from grave heart failure.[7] At each return of the cardiac asystole there was a corresponding return of the paralytic phenomena in the right limbs with transitory aphasia.

(*d*) *Narcotic and other poisons introduced from without.*—Many cases are on record in which poisoning by stramonium, belladonna, cannabis indica, tobacco, and opium have, among other symptoms, given rise to temporary aphasia, and sometimes to amnesia verbalis. References to cases of this kind, and also as to the effects of snake poison, will be found in Bateman's work.[8] Concerning the latter he says: "M. Ruftz stated at a meeting of the Paris Anthropological Society that he had seen a certain number of persons who had completely lost their speech in consequence of a bite from a serpent (Fer de lance); sometimes aphasia was produced instantly, and at other times some hours only after the bite; but, what was most remarkable, those who survived the poisoning remained permanently aphasic. Van der Kolk quotes the case of a gunner in the Dutch Indies who was bitten by a serpent called by the natives 'oeloer'; in a few minutes he became giddy and lost the power of swallowing, there was total loss of speech, but consciousness was unimpaired; death occurred four hours and a half after receipt of the injury." Wm. Ogle has also written an interesting paper[9] on this subject, showing that loss of speech often precedes loss of consciousness, and that in cases of recovery it may persist for weeks after other symptoms have disappeared. These facts seem to show that snake poison exercises a specially deleterious action upon the speech centres of the brain.

In addition to vegetable and animal poisons, however, it has been found that one mineral poison at least—namely, lead—may also produce aphasia. Thus, cases have been recorded by Heymann[10] and others showing that among the various nervous symptoms producible in different persons by lead poisoning aphasia is to be included.

(*e*) *Poisons engendered within the system.*—Under this head we have to include a very miscellaneous group of cases in which aphasia occurs as a temporary symptom in the course of certain specific fevers, in the puerperal state, in diabetes, Bright's disease, gout, &c.

The specific fevers in association with which aphasia is apt to manifest itself as a temporary symptom are typhoid fever more especially, and more rarely in typhus fever, small-pox, measles, and yellow fever. Numerous instances of this kind have been recorded.[11] It has also been met with in association with intermittent fever.[12]

Transitory aphasia may likewise occur in association with the puerperal state, and more frequently after than before delivery. It is then, in all probability, mostly due to minute thromboses. Instead of being transitory, however, it may be permanent and associated with thrombosis of the middle cerebral artery, a good instance of which, as it appears to me, has been recorded by Bateman.[13]

In diabetes, in Bright's disease, and in gout we also have poisonous or other products accumulating within the body, and in each of these conditions nervous symptoms of various kinds are apt to show themselves in different individuals, among which a transitory aphasia is to be included.[14]

In these different cases of poisoning (whether of extrinsic or of intrinsic origin) the precise mode of production of the aphasia probably varies a good deal. In some cases (1) the altered quality of the blood may favour the occurrence of small or temporary thromboses in the vessels of the cortical centres at fault; in others (2) the poisons circulating in the blood may lead to contractions of the small arterioles, thus temporarily cutting off more or less completely the blood supply of these same cortical centres; while in other cases it may be due (3) to the direct action of the various poisons upon the nerve elements of the cortical centres affected.

1. That the first mode of production of the transitory aphasia in these cases is a frequent one there can be little doubt. But such minute thromboses would, strictly speaking, belong to the category of organic causes, and the cases in which they occur are only liable to be confounded or classed with cases of functional disease by reason of the brief duration of the trouble to which they give rise, this brief duration being dependent upon one or other of two conditions; either (*a*) that the thromboses occur only in small vessels, so that the functional effects thus caused can soon be minimised by the opening up of collateral anastomoses; or else (*b*) by the fact that the small thrombosis is temporary, soon becoming resolved. These cases in which the thromboses are minute are connected, however, by insensible gradations with others where larger vessels are occluded and remain permanently blocked, so that the disabilities thus caused not only persist, but are of a much graver kind. And in all the previously enumerated causes of blood poisoning of intrinsic origin it is well known that thrombosis of larger cerebral vessels is apt to occur. In this way aphasia may be associated with hemiplegia, or hemiplegia may occur alone, and they may both persist long after convalescence from the original malady has been established.

2. Cases of transitory aphasia due to spasm of the arterioles would have a more distinct right to come into the category of functional cases, but with what frequency this mode of production occurs we are quite unable to say. Uric acid in the blood is said by Haig[15] to have a tendency to contract the small arterioles, so that this mode of pathogenesis may obtain in some of the cases of transitory aphasia occurring in gouty subjects—the case of frequently recurring aphasia recorded by Daly, and previously quoted, being perhaps a notable example.

3. Instances of transitory aphasia due to the direct action of poisons upon the nervous centres would have an equal right to be placed in the category of functional cases. We may suppose that the poison for the time being annuls or badly hampers the functional activity of one or more of the cortical speech centres, though what determines the noxious influence of the poisons upon these particular sets of nerve elements rather than upon others must remain as obscure in this as in other cases where general causes produce particular local effects.

In other classes of temporary aphasia about to be referred to the actual mode of pathogenesis would seem to be no less obscure, though in some of them it would be commonly said to be due to "exhaustion" of nerve elements following upon epileptiform discharges; or else, in still other cases, to an even more mysterious process known as "inhibition," to which some are very prone to appeal where explanation is difficult.

(*f*) *Before or after epileptiform convulsions.*—It is now a familiar fact that in cases of epileptiform convulsions of the Jacksonian type, whenever the convulsion begins with twitchings about the right side of the mouth (in right-handed persons), or with sensations and twitchings in the tongue, that aphasia may precede and follow for a more or less brief period the occurrence of each of such fits.[16]

Delasiauve[17] has recorded the case of an epileptic woman in which aphasia alternated with epilepsy. She would be aphasic for a week, when on the occurrence of a fit of epilepsy the power of speech would return, paralysis of the bladder, however, ensuing. After a time she would again lose her speech, and the same sequence of symptoms would recur.

Sometimes slight temporary loss of speech has been known to recur two or three times as early events in a chain of symptoms which have subsequently developed into those of general paralysis of the insane. I have recently met with two such cases, and subjoin a few details concerning one of them.

CASE 4.—A merchant, aged thirty-one years, had experienced a great shock and prolonged anxiety in connexion with his business affairs four years previously. This was followed by insomnia, which had become much worse during the last eighteen months.

[16] Occasionally after an epileptic fit an abiding aphasia, without hemiplegia, may be produced, an instance of which has been recorded by Gairdner (Glasgow Medical Journal, May, 1866); whilst in another case recorded by Llewellyn Thomas (Brit. Med. Jour., Sept. 18th, 1875) a child of three and a half years became dumb, and also absolutely deaf, after an attack of convulsions.
[17] Quoted by Bateman, loc. cit., p. 269.

Digitized by Google

I saw this patient first on Feb. 14th. 1894, and was informed that one month previously there had been, without any apparent cause, loss of speech for a time. During this attack he could not get any words out, only making abortive attempts to do so. After about two hours this difficulty ceased rather suddenly, and afterwards he felt even better than he had been before.

Again, five days before he came to me he had another slight attack of the same kind, which lasted for about half an hour. No cause could be assigned for this attack, except that the previous night had been an extra bad one.

On Feb. 24th, after a little extra work in his office, he had another attack of loss of speech (though the loss was less absolute than before) which lasted about one hour. Up to this date there was no paresis of the limbs and no mental symptoms, though there was very slight thickness of speech during the intervals between the attacks.

This patient improved greatly for a time in all ways; but early in April he began to have difficulty in writing letters—omitting words or repeating and spelling them wrongly. By the end of April he became more restless, over-exerting himself, and would not be controlled in this respect. By the middle of May he began to develop delusions of grandeur, which rapidly increased; and on May 26th he was sent to an asylum in a very excited state and full of delusions of all kinds.

It should be borne in mind, likewise, that a temporary aphasia may occur in the course of general paralysis of the insane, as an immediate sequence of one of the so-called "congestive attacks" to which these patients are liable.

In other cases, as will be seen presently, a different form of speechlessness—namely, "hysterical mutism"—is found to follow some attacks of convulsion of an hysterical type.[18]

(g) In association with insanity, catalepsy, and ecstasy.—A condition of mutism of more or less duration is not at all uncommon in patients suffering from chronic dementia or from melancholia. It is often a lack of will to speak which leads to taciturnity extending over long periods, though various other forms of speech defect are also met with among the insane.[19]

Not unfrequently this persistent mutism is the result of some hallucination or delusion. Speaking of this class of cases Séglas says:[20] "Often it is a special hallucination which is the origin of the patient's mutism. He hears, for example, an imperative voice which forbids him to speak; and in spite of all entreaties he keeps silence. In other cases the mutism is the consequence of a delusional idea, which, moreover, may vary in character. Sometimes it is an idea of unworthiness, of humility; the patient believes himself fallen from his position as a man and unworthy to communicate by speech with his fellow creatures. Sometimes it is an idea of expiation; he keeps silence to expiate the imaginary sins that he reproaches himself with. In other cases it is the fear of hurting some one—of compromising, by speaking, some one that he loves—that makes him keep silence. A patient under the care of M. Falret, who had shut himself up in absolute mutism, avowed at intervals that it was for fear of compromising his son by speaking. Sometimes this mutism has its source in an idea of a hypochondriacal nature; if the patient does not speak any more it is because he has the idea that he has no longer a tongue or that his larynx is destroyed."

Many years since an instance came under my own observation in which a semi-demented man had not uttered a single word for several years; he then had a slight attack of pleurisy, and, while suffering from the pain of this affection, he talked pretty freely for several days, answering all questions addressed to him. On another occasion, while suffering from the pain of toothache, he spoke and answered questions for a time, but after the extraction of the tooth at once relapsed into his usual silent and stolid condition. Bateman says that Brierre de Boismont has recorded "the clinical history of a lunatic who had not spoken for thirty years, and who, when perseveringly interrogated, gave a kind of grunt and ran away. About fifteen days before his death he regained the use of speech, and answered perfectly well all the questions put to him."

No mention is made as to the ability to write possessed by the patients above referred to, but in a case cited by Clouston this additional detail is given. This example is instructive also because it illustrates the difficulty of discovering the reason for the silence that exists in many of these cases of what we may call *pseudo-mutism*. Clouston says[21]: "I have a man in the asylum, D. T. K., who for ten years has never spoken a word, but who, I may say, in all other respects behaves sanely, showing no symptom of morbid pride or suspicion. He is about the best joiner we have. We know he has a delusion which prevents him speaking, but what it is we can't find out. If he wants instruction about his work he writes, but nothing will induce him to write why he won't speak."

In reference to catalepsy and ecstacy it is only necessary to say that during the continuance of either of these states the patient remains completely mute, probably from the mere suspension of the will to speak. These cases, in fact, as well as those previously referred to, where the speechlessness is attributable to a lack of will to speak owing to the existence of some determining hallucination or delusion, may well constitute a category apart under the name of "pseudo-mutism."

(h) From fright and other powerful emotions.—Many cases both of temporary aphasia and of mutism have been recorded as resulting from these causes. One cited by Kussmaul[22] is as follows:—

CASE 5.—A girl, aged thirteen years, was run over by a wagon. Although she escaped with some slight scratches she became speechless, and remained so for thirteen months. After various methods of treatment had been tried without success Dr. Wertner at last gave her bromide of potassium. One day, immediately after taking the medicine, she threw herself into her mother's arms and whispered, "Mother, I will speak again." After a few weeks she had entirely regained the use of language.

It should always be borne in mind that in the case of an accident the importance of the mental shock and its consequences often far transcends, as in this instance, the mere physical injury.

Another case of this type has been recorded by Popham[23] which is worth reproducing here.

CASE 6.—A boy, aged fifteen years, received a kick from a cow between the nose and the forehead which stunned him, but left apparently at the time no other injury than a few scratches and slight epistaxis, so that he walked after it some miles to a fair. On the fourth day he was seized whilst at work with vertigo and loss of speech, his hearing, taste, and sight, as well as deglutition, remaining unaffected. A variety of remedies, amongst others mesmerism, were tried, but without any benefit. He continued for twelve months as servant to a medical man, although totally mute, when he got extensive inflammation of the anterior part of the scalp, followed by suppuration, and regained his speech as suddenly as he had lost it eighteen or nineteen months before.

But mere emotion—apart altogether from traumatism—may produce very similar results. Thus Todd[24] refers to the case of a man, aged about fifty-five years, of an irritable temperament, who in a very animated conversation became excited to such a degree that his power of speech was completely lost. There was no paralysis, and the mental faculties were unaffected. He continued in this condition for about one week, but soon afterwards the power of speech had completely returned.

(i) Reflex irritation from neuralgia, intestinal worms, &c.—The pathology of these cases is very obscure, but that such associations are at times met with cannot be denied.

Bateman[25] refers to three cases in which temporary loss of speech occurred in association with facial neuralgia, and also to three other cases where the presence of worms in the intestine was associated with loss of speech which disappeared more or less quickly after their expulsion.

Where a temporary aphasia has been associated with a faecal accumulation in the large intestine, which has disappeared with its expulsion, instances of which have been recorded by R. Jones[26] and by M. Mattei,[27] the cause cannot in all probability be ascribed to mere intestinal irritation. Such cases are rather to be explained as belonging to group (*e*)—"Poisons engendered within the system." They may be supposed to result from the effects of auto-intoxication upon the brain, due to the absorption of alkaloidal poisons from and formed in the overloaded intestinal canal.

(j) By hypnotic suggestion.—Charcot and others have been able to produce typical "hysterical mutism" in some hysterical patients who are capable of being hypnotised. Referring to this subject Charcot[28] says: "I ought to tell you how the phenomena of mutism may be artificially produced. The patient being plunged into the somnambulic stage of hypnotism, you comence by conversing with her for a few minutes, then gradually you approach closer and closer to her, and finally pretend neither to hear nor to understand her. She makes further efforts to speak louder, but you

continue to practise the same ruse, and appear not to understand any better than before. Then it happens that the voice of the subject becomes progressively lower, and in the last stage aphonia becomes complete, and there is an impossibility of articulation. Artificial mutism obtained during the somnambulic period persists as you see in the waking state. I dare not allow this experiment to be prolonged too much, for I have remarked on many occasions that hysterical symptoms artificially produced during hypnotism are more difficult to be made to disappear in a waking state in proportion as they are allowed to persist for a longer time."

(*k*) *Hysteria.*—The cases of temporary speechlessness that occur in hysteria belong almost solely to the type which I have previously referred to as "*hysterical mutism.*" These cases are now commonly known by that name, though they were formerly included, with others, under the more general head of "functional aphasia."

The name "hysterical mutism" was first given to such cases by Revilliod, of Geneva, in an important memoir[29] dealing with this subject, though both the condition and the name were subsequently made more widely known by Charcot[30] in his lectures, as well as by a collection of twenty cases published by his assistant, M. Cartez.[31] Subsequently another series of cases was recorded by Bock,[32] of Berlin, and a still more important collection of eighty cases by Natier,[33] of Bordeaux.

The subject has also been recently considered by Wyllie,[34] who has thrown further light thereupon, and has lent his support to a view first advanced, I believe, by Liouville and Debove,[35] to the effect that hysterical mutism is only a rarer and more aggravated form of a condition which is familiar enough as hysterical aphonia. This doctrine was also adopted by Charcot. As Wyllie[36] says, Charcot shows "that there are many features shared in common by hysterical aphonia and hysterical mutism. They occur in the same type of patients, are produced by similar exciting causes, and are not unfrequently found to alternate with each other in the same patient, the aphonia in some cases passing into mutism, and the mutism in others passing into aphonia. Obviously the mutism is the more severe condition of the two. It implies absence even of the power of whispering, as well as that of speaking aloud."

Some of the leading peculiarities of hysterical mutism are these. Its onset is generally sudden, and often after a fright or some strong emotional disturbance. Sometimes it follows an hysterical seizure, either with or without paralysis of limbs. At other times it occurs without assignable cause, or it may be induced, as already stated, in some hypnotised persons by suggestion. The subjects of this disability are completely mute—presenting in this latter respect a notable contrast to ordinary aphasics, who so frequently make use of recurring utterances or articulate sounds of some kind. The intellect seems unimpaired, and they are able freely to express their thoughts by writing.[37] Though the common movements of the lips, tongue, and palate are preserved, these parts (constituting the oral mechanism) are unable to act in the particular combinations needful for speech movements, in association with the other combinations of muscular action pertaining to the vocal mechanism. Some of the muscles of the larynx, however, are often found to be more or less paralysed, though the particular muscles involved have varied in different cases. Sometimes it has been the crico-thyroids alone, or these with the thyro-arytenoids; in others the arytenoids, or even one only of the adductors has been at fault; and Cartez adds[38] that in certain cases "one may see variations of the laryngeal troubles supervene in the course of the malady without any modification in the mutism."[39] There is also often more or less complete anæsthesia of the larynx and of the pharynx.

Sometimes hysterical mutism occurs in association with many hysterical stigmata; at other times it may be almost the sole manifestation of this neurosis.

Recovery may occur suddenly, perhaps after a fit or a recurrence of some strong emotion; or it may be more gradual, under treatment; and in some of the latter cases there may be a sort of stammering articulation for days, or even weeks, before speech is completely restored.

In illustration of the condition generally, and of the very important fact of the alternation of aphonia and mutism that exists in some patients—which of itself helps to show that the two conditions, if not different degrees of the same affection, are at least very intimately related—the two following cases may be quoted from Cartez,[40] the first of them having been recorded by Thermes,[41] and the second by Liouville and Debove.[42]

CASE 7.—A woman, aged twenty-one years, on Feb. 15th, 1876, after exposure to damp cold—at least, according to the patient's account—was taken with a fit of coughing, and soon after the voice became modified both in quality and intensity. Laryngoscopic examination (by Isambert) did not reveal any organic lesion or inflammatory condition, and the diagnosis was "paralysis of the vocal cords from defective innervation of the muscles of the larynx, and particularly of the crico-thyroids." Consequently, the induced current was advised and applied by Isambert himself. But instead of the usual amelioration, as expected, the aphonia rapidly developed into a mutism. Many varied medicaments were employed, but without effect.

During treatment at the thermo-resinous baths we had the opportunity of examining the patient, and certain objective and subjective symptoms caused us to suspect the case to be one of mutism grafted on to hysteria of a non-convulsive form; or rather, a case of hysteria the manifestation of which had invaded the laryngeal region and particularly the tensor muscles of the vocal cords.

The laryngoscopic examination then made (February, 1877) by Krishaber revealed that the left vocal cord was immobile, and that the free border occupied the median line and divided the glottic space like the perpendicular in an isosceles triangle. The corresponding arytenoid did not perform movements of rotation on its axis. The left vocal cord seemed shorter than the other, because of its laxity and because it was hidden by the arytenoid. The pharynx was slightly hyperæmic.

Hydrotherapy was prescribed. At the first application there was a cry of surprise; the mutism was changed into incomplete aphonia. After a dozen local and general douches, the aphonia gradually disappeared, and a fortnight after the first douche the voice resumed its normal character and intensity.

Under the influence of a fall a convulsive attack occurred, on coming out of which the voice was again lost and the mutism again became complete. This happened in 1877.

In February, 1878, the mutism was still complete. Hydrotherapy, as on the first occasion, produced the same result. The patient cried out and instantly regained her voice, but only for a moment. However, incomplete aphonia succeeded the mutism. She was able to whisper, the words being weak and low, but she could be well understood. Amelioration progressed to cure, and the patient at the time the case was published had not relapsed for ten months.

This is a particularly interesting case, not only because of the transitions that were shown between aphonia and mutism, but because of the varying condition of the larynx and the relapse after a convulsive attack. The next case is also an interesting and important one.

CASE 8.—The patient was a girl, aged eighteen years, hysterical, but generally of good health. Her mother had attacks of hysteria major. A sister, thirteen years old, had frequent attacks, and for two months she had been affected with trembling, which several medical men had regarded as hysterical chorea. The father was very nervous.

Until the last few years the hysteria had only been manifested by incomplete attacks. For eighteen months the patient had been painfully impressed by the quarrels and violent scenes between her father and mother, and it was to this cause that she—probably with reason—attributed her symptoms. About this time, in fact, she became aphonic, not being able to speak above a whisper, and in the course of two months the aphonia grew into mutism. In the house where she lived they named her "the mute." She communicated with those around her by means of a slate, which she habitually carried. The patient came several times into hospital. All those who examined her were agreed in the diagnosis of hysterical paralysis of the vocal cords. Different methods of treatment were adopted without success.

On Nov. 10th, 1875, she was taken to the Hôtel Dieu. She had no globus hystericus, no hemianæsthesia, and no affection of the organs of special sense. The ovaries, especially the left, were tender on pressure; but, briefly, apart from the laryngeal troubles and the ovarian pain, the patient presented nothing abnormal.

The laryngeal paralysis was not simply a paralysis of movement, it was also a paralysis of sensation. There was not the least pharyngeal reflex. Laryngoscopic examination by Dr. Moura revealed a paralysis of the vocal cords; these made an almost imperceptible movement when the patient tried to emit a sound.

Pressure over the ovary brought on attacks of dry cough and a few stifled cries. The patient was able to articulate these words in an almost imperceptible voice, "You hurt me." The following day the compression was continued (from five to ten minutes each time), and intonation became more and more distinct; she first ceased to be aphonic, then to be mute. She became able to speak, though in a low voice, hissing out her words.

Two cases may also with advantage be quoted here which

were recorded by the late Dr. Ernest Jacob.[43] They will serve amongst other things, as instances of the affection occurring in males, as well of its ready cure under the influence of ether.

CASE 9.—"A man, aged about fifty years, applied for relief at the out-patient department of the Leeds Infirmary, bringing a paper on which was written: 'I have pain in my shoulder; I can hear, but not speak.' The history, obtained subsequently, showed that he had had fits in infancy, but enjoyed good health till he was thirty-four years of age, when after monetary losses he began to show signs of mental instability, violent temper, &c., and when agitated was unable to speak. He gradually became perfectly dumb, though he retained for some years the power of saying 'yes' and 'no.' For the last five years he had not spoken, communicating with his wife by means of signs and writing, but understanding perfectly what she said. He seemed quite intelligent, could cough and blow out a candle. He resisted laryngoscopic examination, but I was able to ascertain that the cords could be approximated, and occasionally a hoarse sound uttered. There was no attempt at articulation, though he willingly made attempts when urged to do so.

"The pain in the shoulder was found to be due to dislocation. No account could be given of this, except that six days before he had wakened in the night and found his arm in pain. (In all probability he had had an epileptic fit and fallen out of bed.) Thinking to investigate the aphasic symptoms later, I asked my surgical colleague, Mr. W. H. Brown, to reduce the luxation. To facilitate this ether was administered, and on recovery from the narcotism he began to speak clearly and volubly, evidently much pleased at recovering his power of speech, and determined to make up for lost time.

"Some weeks after, when I saw him again, he was speaking well. I wish to point out here that there was no wilful dumbness, such as is not uncommon in cases of insanity. The man was greatly pleased at recovering his power of speech; nor was there the entire loss of phonation which obtains in functional aphonia, though there was great want of tension of the vocal cords. The patient was not morose or melancholic, though occasionally giving way to passion."

This case is remarkable on account of the rapid and complete recovery of speech, although the dumbness had existed for five years; that is, there was none of the stammering or hissing articulation that sometimes exists for a time when hysterical mutes first begin to regain their speech. In the next case the mutism had been of very brief duration.

CASE 10.—"A healthy-looking miner, aged thirty-four years, applied on Jan. 13th, 1890, suffering from slight hoarseness, and his cords were injected. He gave a history of having had some epileptic fits eight years ago (six in all), and at one time he had been intemperate. Some zinc chloride was applied to his larynx and a pine-oil inhalation prescribed. A week later he appeared with a paper on which was written: 'Five days ago I lost my voice. I feel as well as ever I did, but I have not been able to talk, and I cough.'

"Inquiry showed that he had been quietly talking with some friends on no very exciting topic, feeling rather hoarse, when he was suddenly seized with dumbness. His larynx was now rather difficult to examine, but the cords could be approximated without tension and an occasional hoarse grunt elicited. After a few trials he managed to utter one or two vowel sounds. Remembering the effect of the anæsthetic on the former case I had ether administered. After he had taken one or two breaths the inhaler was removed and he articulated 'Yes' in answer to a question, and after recovery from narcotism could talk freely. He remained an out-patient for a few weeks, but there was no return of the dumbness."

Here the mutism was not absolute, and being only of brief duration the principal interest of the case lies in the prompt restoration of speech after the inhalation of ether.

In the instances cited examples have been given of the recurrence of mutism on two or three occasions. At times, however, the attacks recur again and again, and the duration of each attack is then often very brief. Thus Delasiauve[44] has related the case of a woman who for three years was at each menstrual period affected with mutism and partial paraplegia, being at these times only able to make herself understood by signs. Bateman[45] records an interesting case of his own occurring in a young man who in the course of six months had nine attacks of mutism, most of which lasted only a few days, though one of them remained for over six weeks. Each attack began with sudden pain in the occiput and nape of the neck of an extremely severe character, and the pain was associated with contraction of the muscles at the back of the neck. A still more remarkable case has been recorded by Hun,[46] in which frequently recurring attacks of mutism were generally associated with deafness or blindness, one or both, these disabilities often ceasing after an attack of hysterical convulsions.

During the present year I have also had under my care a patient who had suffered from an extraordinary number of attacks of mutism extending over a period of more than eighteen months. They occurred in a sailor who had not hitherto suffered from nervous symptoms and had previously led an active life in all parts of the world. He was sent to me by Dr. Allan Mahood of Appledore, North Devon, and the following is an abstract of notes received from him and of others taken whilst the patient was under my care at the National Hospital for the Paralysed and Epileptic.

CASE 11.—The patient, aged thirty-one years, had for a time been out of work, worried, and been having insufficient food, when, on July 13th, 1895, he had in the evening a sudden attack of "shaking," characterised by small, rapidly repeated contractions of the muscles of the face, body, and limbs, lasting some hours, but without loss of consciousness. Under treatment and with rest in bed he improved much during the next week, but on July 20th a political procession went past his house, cheering wildly, after an election. This awoke him and gave him a great fright, resulting in complete loss of speech for one hour, together with much twitching of the muscles on the right side of the face.

During the next month he had very many brief attacks of complete mutism. He was rarely many days without one, and sometimes had two or three on the same day.

On Aug. 13th irregular spasmodic contractions of the limbs occurred without loss of consciousness, lasting off and on for nine hours.

On Sept. 4th there were violent convulsive movements of the shoulders, arms, and upper half of the trunk for one and a half hours.

During the next six months he had similar attacks lasting from ten to fifteen minutes, several times daily. The "shaking" was mostly on the right side of the body. He generally lost his speech during the attacks—though on several occasions the mutism lasted for a week at a time, when he communicated with others only by writing and signs. Sometimes he has lost his speech without having an attack of "shaking"—especially under the influence of excitement from any cause. He had a good deal of worry during this time.

On May 8th, 1896, he seemed quite well. There had been no return of the old symptoms during the last month. He went, therefore, for a month's drill with a corps to which he was attached, and after that was about to resume his sea-life, when suddenly his old symptoms returned, and he continued to have "shaking" fits and frequently recurring attacks of mutism up to the date of his entry, under my care, into the National Hospital for the Paralysed and Epileptic on Jan. 13th, 1897. In the early days of this latter month he had the most violent attack of all. He had to be restrained for four hours. He did not hurt himself, but bit his brother severely in the face. Three days before admission he lost his speech entirely on being told he was coming to the hospital, and did not regain it till twenty-four hours after admission.

On admission he was found to be completely mute, though he made a few inarticulate noises on attempting to speak. He was perfectly sensible in all respects—could understand everything said to him quite readily and write his answers on a slate, as well as understand quite well what was written by others. There was no motor or sensory paralysis. His gait was normal. There was some facial overaction on attempting to speak. The eye movements, pupils, and optic discs were normal. There was no contraction of the visual fields.

During the first six weeks of his stay in the hospital he was treated with tonics and tepid needle baths; then with sulphur baths together with bromides and other drugs internally. In this period he had only one slight "shaking" attack two days after admission, and nothing notably wrong apart from some slight tremors about the hands and face at times was noticed, except that he continued to have frequent attacks of mutism lasting for some hours or even a day or two.

I then left instructions that during the next attack he should be put under the influence of ether, and on March 2nd I received a report from the resident medical officer (Dr. W. J. Harris) announcing that on the previous afternoon the patient, after some slight difference with another patient, had again suddenly lost his speech. When seen about half an hour afterwards he could not make any sound, not even "Ah." His larynx was examined again and found to be, as before, very hesitating in adduction, with never complete closure of the rima glottidis. The administration of ether was then commenced. "He took it quietly for about three minutes, until just beginning to feel its effects, when he suddenly bounded off the bed, upset everything around, fought wildly, and was with difficulty subdued—uttering no sound, however. He then lay quiet till let go, when he suddenly attacked us again, and when again subdued he began to talk quite well, declaring he could not help it, &c."

Though he remained in the hospital subsequently for over five weeks he had no further attack of mutism and only one threatening, after some slight annoyance. On April 11th he discharged himself, against advice, on the plea that another patient was noisy at night.

We must now look a little more closely into the pathogenesis of mutism.

From the point of view of the physiology of the two conditions aphonia and mutism, Charcot attempted to draw too sharp a distinction. He adopted the doctrine that has been taught by Marey and other physiologists, that whispered speech is the product of the oral division of that mechanism alone, and that the larynx takes no part in its production. According to Charcot, therefore, aphonia (in which the power of whispering is preserved) is a result of a partial paralysis of the adductor muscles of the larynx; while as to hysterical mutism, he writes. "If the individual suffering from the affection is unable to whisper, it is not because he is aphonic, or rather because his larynx does not vibrate; it is not because he has lost the common movements of tongue and lips—you have seen that this patient was perfectly able to blow and to whistle; it is because he lacks the ability to execute the proper specialised movements necessary for the articulation of words. In other terms he is deprived of the motor representations necessary for the calling into play of articulate speech."

Wyllie, however, contends (and he is supported by the opinion of Michael Foster) that the larynx does take part in whispering, and that there can be no speech without the

Digitized by Google

coöperation of both the oral and the laryngeal mechanisms. He consequently holds that "the disablement of either the one mechanism or the other may produce mutism." In opposition to Charcot and Natier, therefore, who believe the oral division of the speech mechanism only to be at fault in hysterical mutism, Wyllie maintains that whilst this may be so in some cases, in a second group it is the laryngeal division of the speech mechanism which is at fault; and in a third set of cases both oral and laryngeal mechanisms are simultaneously disabled.[47] He refers[48] to various cases in Natier's list in support of his opinion.

I formerly thought that these cases of mutism were instances of complete aphemia, dependent upon a functional defect in the outgoing fibres just below the left third frontal gyrus,[49] because cases of sub-cortical defect, where there was no damage to either of the word centres, at that time seemed to me alone capable of producing the particular combination of symptoms met with in hysterical mutism. And, as in hysteria the afferent fibres in the "internal capsule" appear to be so frequently affected in the production of hemianæsthesia, there seemed no valid reason why the same kind of disability (whatever its nature) might not at times affect some of the bundles of fibres proceeding from, rather than going to, the cortex. Though this was the hypothesis formerly advanced by me, I always recognised that it would have been more satisfactory if one could have supposed that in hysterical mutism portions of the cortex itself were at fault. The bar to this explanation, however, was the undiminished ability to write which these patients displayed and the supposition that an affection of the glosso-kinæsthetic centre would cause some mental impairment of which there was no trace in hysterical mutism.

An examination of the records of actual cases of sub-cortical lesions, and the finding that in some of them where there was destruction of the first part of the geniculate fasciculus and also of the commissure connecting the left with the right third frontal convolution, a mutism was produced almost exactly similar to that met with in the hysterical cases, seemed to be a further justification of my previous view.

On the other hand, a remarkable case recorded by Guido Banti has since convinced me that the symptoms may not be different even when an organic lesion exists in the posterior part of the left third frontal convolution itself, so long as it is absolutely limited thereto, and leaves the cheiro-kinæsthetic centre uninjured. This very important case, which I have previously quoted,[50] shows that in some individuals (besides the preservation of ability to write) the destruction of Broca's region alone may not interfere with the general intelligence any more than does a lesion in the bulbar speech centres or in the internuncial fibres between them and the third frontal gyrus. But if such may be the case with regard to organic lesions in Broca's region we may all the more readily admit that a similar absence of agraphia, and a similar preservation of intelligence may result from a functional disability affecting Broca's region. We have seen, in fact, that the existence of such a disability was Charcot's explanation of the condition. He considered hysterical mutism to be an instance of pure "motor aphasia," resulting from a functional trouble in Broca's region.

This, however, is by no means an adequate explanation of the condition. As we have seen, Charcot too sharply distinguishes hysterical mutism from aphonia, and believes mutism to depend only upon a disorder involving the cortical centre for the oral division of the speech mechanism. The probabilities, however, are against this view, as Wyllie has shown. Aphonia and mutism are most intimately related, differing in degree only; and the oral and vocal speech mechanisms are probably concerned in all speech, whether it be sonorous or whispered. Still we must suppose that the cortical speech centre in Broca's region, which I name the glosso kinæsthetic, is, in reality, composed of two parts most intimately related, both functionally and structually—one of them being the centre for the oral mechanism, and the other the centre for the vocal speech mechanism.

At first it was thought, from the experiments of Semon and Horsley[51] upon monkeys, that the adductors of the larynx were alone represented in the cortex, and that in the anterior part of the foot of the ascending frontal; but Risien Russell[52] has since ascertained that the abductors are also represented in a region slightly removed therefrom. In answer to a query of mine Russell writes:—"In the dog and cat the abductor centre is situated in front of, and a little above, the level of the adductor focus, so that probably the same holds good for man; but I do not wish to commit myself on this point till I have had more opportunities of ascertaining the relative position of these two centres in monkeys." He, however, confirms the statement of Semon and Horsley that there is a complete bilateral representation of the laryngeal movements in the cortex, so that destruction of the centre on one side will not produce paralysis of the muscles of the opposite side of the larynx, seeing that they can still be called into activity by the uninjured centre in the opposite hemisphere.

If a similar bilateral representation of the laryngeal movements concerned with speech exists in man[53] it would follow that to account for hysterical aphonia, characterised by paresis of the laryngeal adductors, we must suppose that the corresponding centres of both hemispheres have been simultaneously affected, and somewhat degraded in functional activity.

As I have already pointed out, however, it has been shown that hysterical mutism is intimately related to aphonia; and therefore mutism might be supposed, even for this reason alone, to be also due to a bilateral affection of the cortex. But we shall now see that there is another reason pointing in the same direction. Charcot's explanation of hysterical mutism does not account in any way for the fundamental difference that exists between it and ordinary simple aphasia. The subject of the former affection is, as we have seen, absolutely mute, and has no "recurring utterances" of any kind. It is commonly supposed that in ordinary aphasia, due to a lesion in Broca's convolution, the recurring utterances are brought about through the instrumentality of the right hemisphere. The same thing would, therefore, doubtless occur in the functional affection if the left third frontal convolution were alone involved, but as instead there is absolute dumbness, we are, I think, on this account bound to assume that in this disorder, as in aphonia, there must be a simultaneous affection of the posterior part of the right as well as of the left third frontal convolution.

Charcot does not attempt to explain the above-mentioned important difference between the two affections. As I have already indicated, he regards hysterical mutism as due to a functional defect in a part of Broca's centre in the left hemisphere—namely, the part having to do with the oral mechanism for speech. The only additional remark that he makes on this subject occurs towards the close of his lecture, where he says: "It is in the grey cortex of the cerebral hemisphere that we must seek for the dynamic lesion whence emanate the symptoms in question, and the mechanism that is to be invoked in such conditions is none other than that which acts in the production of psychical or, if you like it better, mental paralysis." This is rather vague, and introduces no further explanation of the pathogenesis of the condition. Will, except in regard to speech, does not seem to be defective or hindered in its manifestation, and we have evidence also that in these patients the other word-centres—namely, the auditory, the visual, and the cheiro-kinæsthetic, are in a condition of unimpaired activity.

Thus the clinical differences between simple aphasia and hysterical mutism force us to the same kind of conclusion as to the pathogenesis of the latter affection, as that to which we are also led by a consideration of the intimate relations existing between it and hysterical aphonia. It impels us to believe in the existence of a bilateral cortical disability in Broca's region in each of these affections, though varying in intensity in the two cases. This explanation, I believe, has not hitherto been adduced for either of these affections.

It will be observed that hitherto I have neither adopted nor definitely referred to the hypothesis of Wyllie as to the existence of certain subdivisions of what he calls Broca's convolution. I say "what he calls Broca's convolution," because instead of limiting this region, as is

[47] His views as to the cortical localisation of these mechanisms will be subsequently considered.

[53] This cannot, however, with certainty be considered to follow from the fact that experiments upon lower animals show that common movements of the larynx are bilaterally represented.

Digitized by Google

customary, to the foot of the third frontal convolution, Wyllie seeks to include under it also the foot of the ascending frontal and the foot of the ascending parietal convolutions.[54] He suggests that in these two latter sites the "executive cortical motor mechanisms" concerned with speech are to be found—comprising a "centre for phonation" and a "centre for the oral articulative mechanism"; while in the foot of the third frontal are stored up the "guiding psycho-motor images for spoken speech," or, in other words, what I have termed "glosso-kinæsthetic impressions." These views have been accepted and still further elaborated by Elder,[55] who also reports one case which he thinks "goes a long way to support the hypothesis of Wyllie."

Now in regard to the impressions registered in the foot of the third frontal convolution it would appear, as I have said, that Wyllie's "guiding psycho-motor images" correspond with what I term kinæsthetic impressions, and further that these impressions resulting from speech movements must partly correspond with impressions from the oral and partly from the vocal subdivision of the speech mechanisms. These, according to my view, are the guiding sense impressions which (in conjunction with auditory word-images) act directly upon, and are capable of evoking the proper activity of, the bulbar motor centres. I therefore do not believe even in the existence of the "cortical executive motor mechanisms" for speech which Wyllie and Elder assume to exist at the bases of the ascending frontal and ascending parietal convolutions; and further I consider that the reasoning which induced Wyllie to suppose that such centres might be thus situated is of itself open to very grave objections.

He seems to have been guided altogether too much by the results obtained by experimental physiologists (Ferrier, Semon, Horsley, and others) upon monkeys and dogs, and not to have kept distinctly in mind that the movements of the larynx resulting from stimulation of the cortex in these dumb animals could not have been such movements as were concerned with speech, though they might have been the reproductions of much less specialised movements of the vocal cords (adduction and abduction) associated with respiratory acts; and, again, that the movements of the lips, and tongue similarly induced in these dumb animals could not afford any evidence as to the site of the "oral articulative mechanism," although they would serve to determine the seat of registration in such animals of the impressions resulting from the common movements of these parts concerned with biting, mastication, &c.

The very fact, however, that such common movements are registered in these sites (if it may be considered to hold good for the human subject) would of itself lead us to look elsewhere for the registration in man of the multitudinous impressions derived from the highly specialised movements concerned in speech—for instance they might be found in the contiguous foot of the third frontal convolution. And, as Wyllie himself admits[56] (though in a rather hesitating way), the clinical evidence points to the importance of the foot of the third frontal convolution, and not to the bases of the ascending frontal and parietal convolutions, as the region most concerned with the production of speech. It ought to be almost superfluous to enforce the point that it is upon clinical evidence alone that we must rely for the localisation of speech centres, and not upon the "conclusions of the experimental physiologists" drawn from experiments upon dumb animals.

An attentive study of the case above referred to that has been recorded by Elder, seems to me to show that the lesion was an essentially sub-cortical one, and that all the defects in articulation met with could have been produced by damage to some of the pyramidal fibres proceeding from the foot of the third frontal convolution, even though the lesion also destroyed portions of the bases of the ascending frontal and parietal convolutions.

No real evidence is therefore forthcoming in favour of the hypothesis of Wyllie; and that the distinction which I have dwelt upon between the common movements of the lips, tongue, and palate, and the common movements of the vocal cords, as contrasted with the highly specialised combinations of movements of these parts concerned in speech, is a perfectly valid and important one is shown by the fact that in hysterical mutism though the latter movements are impossible the common movements of the lips, tongue, and palate are quite unaffected—just as in aphonia the vocal cords can be perfectly approximated during the act of coughing, though they cannot be brought together as a component of the movements necessary for speech.

CONGENITAL ABSENCE OR DELAYED DEVELOPMENT OF THE PATELLA.

BY E. MUIRHEAD LITTLE, F.R.C.S. ENG.,
SURGEON TO THE NATIONAL ORTHOPÆDIC HOSPITAL.

AN annotation appeared in THE LANCET of Jan. 23rd, 1897, in which a paper on this subject by Dr. Bristow, of Philadelphia, was summarised.[1] Dr. Phocas and Dr. Potel, of Lisle, have also dealt with it recently.[2] Dr. Bristow described a case of his own and referred to five others which are not, I find, included in the list of twenty-five cases published by Dr. Phocas and Dr. Potel. I have had three cases under my care and have collected records of ten others observed by various writers, making, with an unpublished case of Mr. Adams, which I had an opportunity of examining, forty-two cases in all. In addition to these I have, by the kindness of Mr. William Sedgwick, a note of a family, in four generations of which eighteen persons had no patellæ and no thumb-nails; the majority of these were females. This deformity is generally associated with hyper-extension of the leg upon the thigh and with limited flexion of the knee. The amount of hyper-extension varies from a few degrees or slight subluxation to complete anterior dislocation, as in Hilton's case. In some cases the knees have been so stiff that the condition might be described as one of ankylosis. Talipes and especially varus is frequently present. Thus varus was noted in sixteen cases. Other forms of talipes were noted in five cases. Osseous defects such as deficiency of the fibula, spina bifida, and malformation of the hip-joint, and congenital dislocation of the hip have been noticed in several cases. In two cases quoted by Dr. Phocas and Dr. Potel the whole diaphysis of the femur was wanting. I have not included these two cases in my table. The condition was said to be hereditary in four cases, three of which have come under my personal notice, besides the eighteen persons of Mr. W. Sedgwick's note, already mentioned. In nine cases the knee-cap appeared at ages varying from six months to six years. In four it was wanting until the end of the period of growth, and in the remaining twenty-nine cases it had not appeared at the time of the last examination. In some cases the patella has been wanting on one side, and rudimentary on the other. It is interesting to note that the adult cases had no severe accompanying deformities, while in some of the cases of severe talipes, &c., the patella ultimately appeared. Only one necropsy is recorded as far as I have been able to learn. In this case (quoted by Dr. Phocas and Dr. Potel from Carl Müller) the flattened tendon of the quadriceps lost itself in the capsule of the joint and the aponeurosis of the leg. Contraction of (or traction on?) this muscle was without action on the movements of the leg. The subject was a stillborn infant. The following are short notes of my three cases (Nos. 40, 41, and 42 in the table).

CASE 1 (see Table, No. 40).—A female child, aged three months, was brought to the National Orthopædic Hospital in September, 1887, on account of severe double congenital talipes equino-varus. She was the first child. The father was operated on for clubfoot, and he and a brother, who died in infancy, are said to have had knees similarly deformed to those of this patient. The father's father was said to have had some deformity of the foot. The family history on the mother's side was negative as far as could be ascertained. The present patient's knees were found to be hyperextended, so that the leg formed an obtuse angle with the thigh anteriorly. With slight force the limb could be brought into the straight line, but flexion beyond this was impossible. The deformity of the feet was corrected, and the knee gradually bent by means of a splint, with thigh and leg plates applied to the front of the limb with a rack movement opposite the knee-joint. In May, 1889, the child could stand alone with the knees hyper extended, although no trace of either patella could be found. A walking instrument which

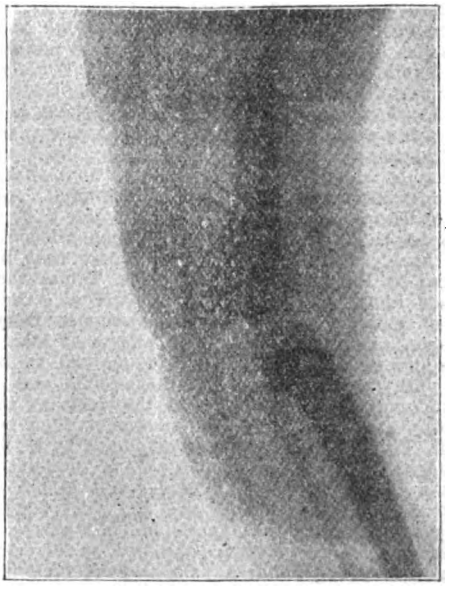
prevented extension of the knees beyond the straight line was applied. In March, 1891, the age of the patient being three and three-quarter years, the right knee-cap was distinctly felt, but there was some doubt as to the left one. The knees were very lax. By October, 1896, both knee-caps were fairly well developed. In February, 1897, the child, who was then aged nine years and eight months, could

FIG. 1.



CASE 1.—Delayed development of patella, from a photograph showing the hyper-extension of the knee-joints.

run about and dance vigorously without difficulty. Her knees were capable of slight hyper-extension, as shown in Fig. 1 (from a photograph), but when standing or walking ordinarily did not pass the straight line. The patellæ were small and the front of each knee looked flat. On examination by the x rays a definite dark shadow was seen on the fluorescent screen in the situation of the patella.

CASE 2 (see Table, No. 41).—This patient, a sister of the foregoing, was brought to the National Orthopædic Hospital in November, 1892. She was the third child. Her condition was almost exactly similar to that of Case 1 (No. 40), except that the knees were flexible to about a right angle. She had double talipes equino-varus, which had been treated already by tenotomy and plaster-of-Paris bandages. The mother thought that the weight of these latter caused the knees to bend. The knee-joints, which were stiff at birth, were loose, and allowed excessive lateral and rotary movements. No trace of a knee-cap could be found on either side. The feet were treated and instruments ordered to restrain the extension of the knees. In August, 1895, she was admitted as an in-patient and Phelps's operation was performed on the right foot on account of relapse. The registrar's notes state that the knees were then almost flail-like and the ligaments were very lax; the tibiæ could be rotated on their long axes through an arc much greater than normal. The right patella was very small; the left could scarcely be felt. In February the child, being then five years and ten months old, could run about actively. The front of each knee appeared flatter than normal. The patellæ were obvious, but small and scale-like. A skiagraph, however, disclosed no trace of them, showing that ossification had not begun, although the tendon of the quadriceps threw a faint shadow, as seen on the concave anterior aspect of the knee in Fig. 2. The knee-joints were loose and allowed more lateral and rotary movement than normal. The knees were not generally hyper-extended, but the application of slight force brought them into the position shown in Fig. 3 (from a photograph in the supine position). In flexing the knees a jar was felt as of a subluxation occurring, or a cartilaginous ridge being passed or a tendon or ligament slipping from one position to another. The knees can be flexed through about 135°, or 45° beyond a right angle.

CASE 3 (see Table, No. 42).—A male child, aged six weeks, was brought to me in October, 1891. He was born by foot or breech presentation. The left patella was normal. The right patella could not be found. The left knee could be hyper-extended, but was flexible to the normal extent. The right knee was hyper-extended and stiff. The left thigh was rotated outwards. There were several deep scars over the buttocks and sacrum. The right testicle was not in the scrotum. There was no paralysis. The family history was

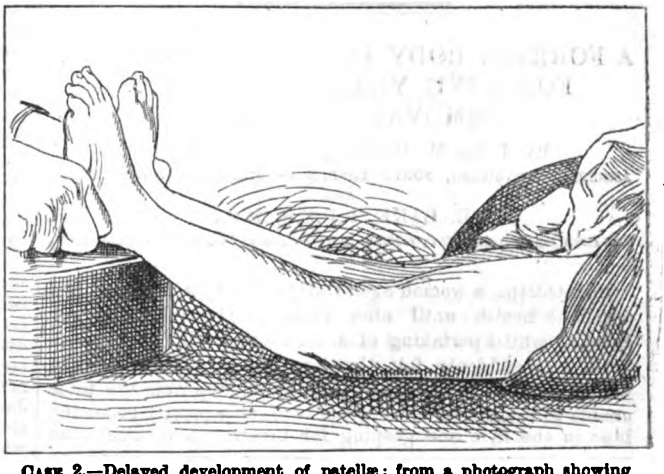


FIG. 2.

CASE 2.—Reduced from a skiagraph by the author. The patella is cartilaginous.

negative. Manipulations were ordered to the hip, knees, and feet, which latter were slightly inverted, but easily flexed and everted. In February, 1892, a splint was ordered for the right knee. In June, 1893, there was some doubt as to the existence of a rudimentary right patella, but in January, 1894, when the child was aged two and a half years, there was no doubt of its presence. In February, 1897, at the age of five years and four months, the child walked well, but the feet were rather flat. The left knee was normal. The patella measured transversely through the

FIG. 3.

CASE 2.—Delayed development of patellæ; from a photograph showing how the application of a slight force would cause hyper-extension.

Digitized by Google

skin one and a half inches. The right knee was flexible to eight degrees beyond the right angle. The patella measured one and a quarter inches across. The movements of the knee (other than flexion) were normal. There was no hyper-extension. The right hip could not be fully flexed, although it could be brought to an angle of 45° with the axis of the trunk. The great trochanters were situated in Nélaton's line.

Remarks.—Dr. Phocas and Dr. Potel attribute the deformity to paralysis of the quadriceps, but it is difficult to understand how such a condition could cause hyper-extension, although the arrested development of the muscle would doubtless affect the growth of its tendon, and contained sesamoid bone. In none of the cases that I have seen has there been any evidence of paralysis, nor does it appear to have been marked in any of the recorded cases. Other writers have sought to explain this and its accompanying deformities by deficiency of liquor amnii and pressure of the uterus preventing flexion at the knees. As Dr. Phocas and Dr. Potel point out, however, the cartilage of the knee-cap begins to appear in the second or third month of fœtal life, before active movements occur. Exactly similar deformities of the knee amounting, as in Mr. Godlee's [3] case, to dislocation may exist although the patella be present. In fact, the presence or absence of the knee-cap is of small practical importance. The accompanying hyper-extension, luxation or subluxation and malformation of bones are the important factors in making a prognosis. As long as the quadriceps tendon is inserted into the tibia the knee seems to be capable of good function without a sesamoid bone. So much is this the case that in a case reported by Bernstein (No. 27 in the Table) the patient did not know of his defect. Beyond a certain shakiness of gait he suffered no inconvenience from it. In my cases, as in others, the good effects of manipulations and appropriate splints have been marked in improving the mobility and stability of the knee-joints, and the effect of the application of weight to the feet, as in Case 2 (No. 41), suggests a mode of treatment that may prove useful. Forced flexion has been employed by L. Sayre and by Salaghi,[4] who ruptured the capsule of the joint and produced a hæmarthrosis. The final result is not recorded. Dr. Bristow and Dr. Phocas and Dr. Potel employed the x rays as a means of diagnosis in their cases, but it is evident that negative evidence obtained by this means is of no value in young children. Cartilage is particularly pervious to these rays, and as the patella does not begin to ossify until the third year we are not likely to find evidence of a bony patella before that age. In Gray's Anatomy, moreover, it is stated that the author examined the patellæ of two children of six years of age without finding any trace of ossification. I have examined the normal knees of several children by means of x rays, and have only succeeded in getting a shadow of the patella in a child aged seven years. In Case 2, where the patella was of fair size, the skiagraph showed no clear evidence of its existence at the age of nearly six years; no doubt ossification was delayed in this case, but more information is apparently needed as to the time of ossification in the normal subject.

Seymour-street, W.

A FOREIGN BODY IN THE AIR PASSAGES FOR NINE YEARS; OPERATION; REMOVAL; RECOVERY.

BY J. LE M. BUNCH, M.D., B.S. LOND.,
ASSISTANT PHYSICIAN, NORTH LONDON HOSPITAL FOR CONSUMPTION
AND
R. LAKE, F.R.C.S. ENG.,
SURGEON LARYNGOLOGIST, NORTH LONDON HOSPITAL FOR CONSUMPTION.

THE patient, a woman aged thirty-eight years, had enjoyed excellent health until nine years previously, when one evening, whilst partaking of some broth made from sheep's head, she suddenly felt that she had swallowed a bone, which "stuck in her throat"; she sprang up from the table unable to breathe for a second or two, subsequently becoming blue in the face and gasping for breath. A medical man was hurriedly sent for. In the meantime the patient coughe a great deal, but expectorated nothing as far as she could remember, but experienced a sensation as though her throat was torn, the breathing remaining very embarrassed for about ten minutes, and she could not speak for fully an hour on account of the cough it excited. A raw egg was administered by a friend with the intention of "making the bone go down." The medical attendant, on examination of the throat, said that he saw nothing, and supposed that the bone had passed into the stomach. During that night the throat felt very sore and the patient coughed somewhat, but she felt well except that she suffered from the effect of the great fright she had received. The next day the patient was very prostrate and weak, and the throat felt very sore, especially on swallowing. The breathing as far as she remembered was quite normal. The practitioner said that she had an ulcerated throat and must keep in bed, which she did for about ten or eleven days. During this time the patient could eat nothing solid on account of the pain caused by deglutition, but the soreness of the throat gradually passed off. The throat continued to be slightly sore for about a month, at the end of which time the patient felt herself again. The patient remained in good health till three or four months afterwards (the beginning of the winter), when a hard, dry cough commenced, which lasted nearly the whole of the winter. This repeated itself every winter, each time getting worse, and soon was accompanied by a pain in her back at the base of her right lung; this she thought was due to the excessive coughing. Last year (1896) the cough became worse than ever before. Since the accident this had been the only trouble that the patient had complained of, but the cough and pain were so bad at times that she had to give up work for a day or two, but on none of these occasions did she seek medical advice. On July 24th, 1896, the patient went from Bristol to Clevedon (eighteen miles), had some fish for dinner, and on going out some half hour afterwards a violent fit of coughing came on. She went back to Bristol, coughing violently all the way, and at the same time bringing up a good deal of blood. Speaking was very painful and her voice was husky. That night, though she was somewhat better, she slept little and coughed somewhat, but did not bring up any more blood. The next day she complained of pain in the back of her head and neck, and the throat again was very sore, especially on swallowing. She went to a medical man, who prescribed for her, and advised her to go to bed. The cough soon ceased, but the throat remained very sore for a week, and the patient felt unwell in herself. The pain in the head and neck lasted about four days. She soon felt quite well again, but noticed that her breathing was becoming difficult and short, especially on exertion; this became progressively worse. In October the breathing was at its worst, and the patient attended the Western General Dispensary; there she saw the house surgeon, who, after examining her throat, asked her if she had ever swallowed anything, the patient replying that she never had; she was treated for the pain in the side. In November she attended at the North London Hospital for Consumption as an out-patient under Dr. Bunch, who prescribed a mixture of iodide of potassium for the tracheal trouble, considering it to be probably specific. She attended for six weeks. During this period she was exhibited at one of the laryngological societies as a case of tracheal stenosis of specific origin. She was admitted as an in-patient, and then complained of cough, thick dark expectoration, and great difficulty of breathing. She was put on one drachm of iodide of potassium daily, the case being still regarded as one of syphilitic tracheal stenosis. One drachm of mercury ointment was ordered to be rubbed into the neck three times a week. On Dec 4th the patient felt better and the breathing was easier. On the 14th there was a slight paroxysm of dyspnœa in the night; her colour was good. On the 18th there was another paroxysm of dyspnœa. On Dec. 18th she was examined by Mr. Lake, who diagnosed a foreign body lying obliquely across the trachea from the right forwards and to the left (Fig. 1)—probably a pin or needle, the ends of which were embedded in an inflammatory swelling, ulcerated at the points of insertion of the body, and causing considerable narrowing of the trachea. On Jan. 22nd, 1897, in the absence of Dr. Bunch, a consultation was held with Dr. Pidcock and Dr. A. MacGregor, when, as there was now most distinct evidence of increased tracheal stenosis, and the patient's respiration was becoming seriously embarrassed, it was decided to ask the opinion of

[3] Transactions of the Clinical Society, vol. x.
[4] Archiv di Ortopedia, 1894, p 222.

Digitized by Google

Mr. Watson Cheyne, the consulting surgeon to the hospital. Accordingly the patient saw Mr. Cheyne on the same day, and he agreed that a foreign body was present and that immediate operation was necessary, which he performed on the 25th. The patient was anæsthetised with $CHCl_3$, but, as expected, she took the anæsthetic very badly, the stridor becoming very marked and cyanosis coming on rapidly. An incision, about four inches in length, was made over the trachea, division of the isthmus of the thyroid being necessary. The patient ceased breathing just as the trachea was reached; it was therefore immediately opened, respiration being promptly re-established. The tracheal wound being enlarged a little upwards part of the foreign body was seen, and it was then extracted, and found to be a piece of bone (Fig. 2) with sharply bevelled edges. A long tracheal tube was pushed down to make sure that there was no further obstruction and some granulation tissue on the right side of the trachea was

FIG. 1.

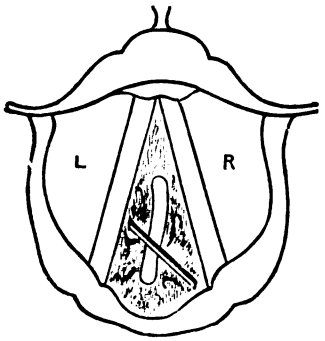

Diagram of foreign body *in situ*; it is drawn too thin and the shadow is on the wrong side.

FIG. 2.

Foreign body (actual size), the right upper side being that seen in Fig. 1.

lightly scraped. A Parker's tube was inserted and two stitches were used to the superficial wound. There was much coughing immediately after the operation, necessitating the withdrawal of the tube, when a large piece of granulation tissue detached by the tube was ejected. On the 26th the temperature was 97·6° F. in the morning. The patient coughed a great deal all day. On the 27th the temperature was 99·2° at 10 A.M., and the pulse was 98. The throat was still painful on swallowing. At 6 P.M. the temperature had risen to 100·4° and the pulse to 104. At 10 P.M. the temperature fell to 98·8° and the pulse to 102; the respirations were 30. The patient was very restless and the cough had become more troublesome. On the 28th the temperature at 7 A.M. was 98·6°. Nourishment was taken fairly; swallowing was rather less painful; the pulse was 96 and the respirations were 28. The patient did not feel so well; she complained of shivering about 11 A.M. The temperature at 2 P.M. was 103·2°, the pulse was 127, and the respirations were 42. The patient coughed a good deal and there was expectoration of glairy mucus. The tube was removed for a quarter of an hour. On examination of the chest behind a patchy dulness was noticed at both bases, but mostly on the right side. Patches of bronchial, almost tubular, breathing were heard, also râles, but this was most marked on the right side. She had had some pain in the right side. On the 29th the patient was much better. The temperature was 99·2° at 7 A.M., rising to 100·8° at 2 P.M. The physical signs had improved; the râles were less in number and less consonating; the breathing was not so tubular. The patient still coughed up a good deal. Counter irritation was applied to the left base. She had a fairly good night and on the whole was much better. The temperature rose to 98·4° at 7 P.M. By Feb. 1st all the physical signs in the chest had disappeared. There was slight cough, but no expectoration. The tube was removed. On the 17th it was noted: "Has been out to-day. Wound quite closed. Normal temperature. Cough better." On the 27th the cough was all right. On laryngoscopic examination a little button of granulation tissue was seen at the upper end of the tracheal wound, and the scar in the trachea was visible. The patient stated that she had not felt so well since she swallowed the bone nearly nine years previously.

Remarks.—We are indebted to Mr. Cheyne for his kind permission to publish this case, and have to thank Dr. MacGregor (under whose care the patient was owing to the temporary absence of one of us) and Mr. C. S. Read (the resident medical officer) for aiding us in preparing these notes. The case is one of extreme interest if, as we imagine, this bone was impacted in the right bronchus for over eight years, and then shifted its position in August, 1896, causing the tracheal stenosis. Its size was 0·82 by 0·60 of an inch, but it was thin, only consisting of the inner table of the sheep's skull. The extreme denseness of the bone was, no doubt, the reason it was able to remain so long unaltered in the body, and its peculiar shape and sharp edges prevented it moving about, and, when viewed from above *in situ*, it gave the impression of a bar.

The number of cases recorded of a foreign body being retained in the trachea or bronchus with recovery after removal or expulsion is thirty-one. The cases in which the

Digitized by Google

foreign body was retained longer than that forming the basis of this paper are three in number. As an example of another class of case—i.e., that in which the foreign body was retained and the patient died from other causes—may be quoted that by J. Mitchell,[1] in which a half sovereign was found at the bifurcation of the trachea many years after it was inhaled.

This table includes every recorded case during the present century that we have been able to find in which the foreign body was present for twelve months or longer, and in which recovery followed either operation or spontaneous ejection. In those cases which do not survive the cause of death is almost invariably tuberculosis. It is but speculation to try to arrive at the factors which conduce to the harmless retention of any foreign body in the lower air passages. Naturally there is the important but vague personal factor, with any tendency to the spontaneous development of tubercle, and probably the environment of the patient; next no doubt comes the position occupied by the foreign body, the most favourable probably being those in which there is absolute immobility, with the minimum of obstruction to the air stream. By the table it will be seen that with two exceptions the foreign body was not capable of absorbing moisture, and so swelling and becoming fœtid.

As to symptoms, they are very vague, the most usual one being pain referred to one side if the foreign body is lodged in a bronchus, but even this is by no means constant, the remainder are much what one would expect, both objective and subjective.

SOME REMARKS ON LAVAGE OF THE STOMACH IN CONNEXION WITH A FATAL CASE OF VOMITING WHILE UNDER AN ANÆSTHETIC.

BY G. BERTRAM HUNT, M.B., B.S. LOND.,
RESIDENT MEDICAL OFFICER TO UNIVERSITY COLLEGE HOSPITAL.

A MAN, aged thirty-seven years, was admitted into University College Hospital with profuse stercoraceous vomiting due to an old femoral hernia which had become strangulated four days previously while the patient was suffering from a slight attack of delirium tremens. The general condition was under these circumstances very unfavourable; vomiting occurred two or three times hourly, the pulse-rate was 144 to the minute, and the man had evidently been a heavy drinker, although there were then no signs of delirium tremens, and no organic disease of the heart or other organs could be detected. He took the anæsthetic—gas and ether given in the larger Clover inhaler—well, except for some struggling. When just passing into the stage of complete anæsthesia some vomit came up into the mouth without any visible muscular straining, the operation not having commenced. Respiration ceased entirely from that moment in spite of the immediate and long-continued application of artificial respiration, sponging out of the pharynx, laryngotomy followed by suction of some vomited matter out of the trachea, and other means of stimulation. Cardiac action certainly continued for a short time after respiration ceased, but the exact moment of its cessation was not ascertained as it seemed inadvisable to stop artificial respiration in order to allow of auscultation of the heart. Altogether about three-quarters of an ounce of the ether had been used. The necropsy showed the loop of gut in the hernial sac to be deeply congested, but not gangrenous. The other organs were healthy to the naked eye, except the lungs, which were œdematous and contained fæculent matter in the smaller tubes.

Remarks.—Death in this case was evidently not due to any toxic effect from the ether and should come under the head of death *under* the anæsthetic, not *from* the anæsthetic. The factor introduced by the etherisation was the abolition of the protective closure of the larynx, so as to allow the inhalation of some of the stercoral vomit due to the obstruction; the flooding of the bronchial tubes with the fluid matter producing immediate asphyxia. Similar accidents during anæsthesia in cases of intestinal obstruction are not uncommon and several are recorded in the Report of THE LANCET Commission appointed to Investigate the Subject of the Administration of Chloroform and Other Anæsthetics from a Clinical Standpoint. They may occur either with ether or chloroform and are more common when the patient is recovering from the anæsthetic than when he is passing under. It seems to be undecided which is the best anæsthetic for these cases, some preferring ether, others chloroform; but in this patient both the strong alcoholic history and the rapid pulse seemed to point to ether, apart from the abdominal condition. For the prevention of vomiting under the anæsthetic which in this class of case frequently occurs unnoticed, being caused by a quiet pumping action of the diaphragm and not by any strong contraction of the external muscles, it is usually recommended to put the patient under as rapidly as possible without allowing any sudden increase in strength of the vapour breathed, and also to keep the head somewhat inclined to one side. Both these precautions were taken, but probably it would have been still better to have administered the anæsthetic with the patient lying on the side, so as to minimise the risk of the inhalation of any vomited matter.

An accident such as this raises the important question of the advisability of washing out the stomach before giving the anæsthetic in any case of intestinal obstruction. It was laid down by such a high authority as the late Mr. Greig Smith, in a paper read before the Royal Medical and Chirurgical Society,[1] that, in any case of intestinal obstruction with a distended stomach either the stomach should be washed out before giving the anæsthetic or a local anæsthetic only should be used; and this opinion seems to have been endorsed by several of the well-known surgeons who took part in the discussion. This advice, however, seems to be by no means generally followed, and a preliminary lavage of the stomach in these cases is not considered by either Dr. Buxton or Dr. Hewitt in their books on anæsthetics. The advantages gained by this means are (1): the removal of a large quantity of poisonous material from the stomach, which if left is in part absorbed, and often causes severe toxic symptoms and sometimes death some hours or days after the obstruction has been relieved by operation; (2) the prevention of vomiting and the inhalation of fluid stercoral matter into the lungs either at the commencement or end of the anæsthesia. Death from this cause may even occur within an hour or so of recovery from the anæsthetic. Thus a case occurred in the University College Hospital in which a typhlitic abscess causing very severe intestinal vomiting was opened and drained; half an hour after the operation was over, when the patient was back in bed, profuse vomiting occurred and death took place immediately. Immediate death from asphyxia is not the only danger from inhalation of fæcal vomit, as if only a small quantity passes through the larynx there is great danger of it setting up severe or fatal septic pneumonia. The advantages of the avoidance of two such very grave dangers are so obvious that lavage would probably be universally employed as a preliminary in these cases if it were not for one serious objection. This is that the necessary manipulation performed on a conscious person often causes so much retching and straining that severe collapse may easily occur, especially as the patient is usually already in a critical condition, so that he is put in a worse position to stand the operation and anæsthetic. This collapse is by no means unknown when lavage is performed on a comparatively healthy person. To obtain the advantages of the lavage and to avoid the danger of collapse the patient may be first put under the anæsthetic and the stomach then washed out, as may be then easily and quickly done without producing bad symptoms. Our intention was to do this in the present case, but the fatal vomiting occurred before he was sufficiently under. It is the method which has been used with very good results in most cases of intestinal obstruction in which I have administered the anæsthetic. The only objection to it is that, as in this case, vomiting may occur while the patient is passing under the anæsthetic. However, vomiting at the commencement is not nearly so common and is more preventable than that occurring after the anæsthesia, at which period nearly all the fatal cases seem to have occurred.

Thus there seem to be three methods of dealing with these cases of intestinal obstruction or other forms of distended stomach in which an operation is required, each

[1] Brit. Med. Jour., June 13th, 1896.

[1] THE LANCET, March 12th, 1892, p. 582.

Digitized by Google

method having its own disadvantages. 1. Not to use lavage, thus running the risk of vomiting producing asphyxia or septic pneumonia, and also of after toxic symptoms due to absorption from the stomach. 2. To perform lavage before giving the anæsthetic, running the risk of the production of collapse, thus increasing the danger of shock from the subsequent operation. 3. To perform lavage as soon as the patient is fully under, taking precautions to minimise as far as possible the danger from vomiting occurring before the stomach is emptied. Although the latter method is useless in a case such as the present, yet it seems to be the one with the fewest disadvantages, and apparently offers the best general way of treating these unsatisfactory cases.

ON THE INCREASE OF THE EOSINOPHILIC CELLS IN THE CIRCULATING BLOOD IN TRICHINOSIS.[1]

BY WILLIAM SYDNEY THAYER, M.D.,
ASSOCIATE PROFESSOR OF MEDICINE IN THE JOHNS HOPKINS UNIVERSITY.

IN the April number of the *Bulletin* of the Johns Hopkins Hospital, Dr. Brown reports some interesting observations upon trichinosis based chiefly upon studies of the blood and muscle of a case which occurred in the medical clinic under our observation. In this communication the remarkable fact was pointed out that the blood showed an enormous percentage of eosinophilic cells, the proportion reaching at one time as high a point as 68·2 per cent. of the entire number of leucocytes. Dr. Brown remarks justly that "the presence of such quantities of eosinophiles suggests their possible diagnostic value in trichinosis." The occurrence of a second case with similar manifestations would appear to justify our suspicions as to the great diagnostic importance of this increase in eosinophilic cells, and it has seemed to me advisable to present here a brief summary of these two instances. The careful studies of Dr. Brown will appear at length in an early number of the *Journal of Experimental Medicine*.

CASE 1.—An Englishman by birth, aged twenty-eight years, was admitted to the Johns Hopkins Hospital on March 3rd, 1896, complaining of general muscular pains and weakness. The patient, who was a reporter by occupation, had been leading the life of a tramp for some time before entry, sleeping at times out-of-doors and often deprived of sufficient nourishment. His family and previous history had no relation to his complaint at that time. For six weeks he had complained of "irregular indefinite pains," as he expressed it, in his joints, bones, and muscles, and for two weeks before entry these pains had been so severe that he had had great difficulty in moving about. There was a feeling of fulness in the head and great muscular tenderness and weakness, so much so that he had to be assisted in putting on his clothes. He was unaware of having had fever. There had been no œdema. Physical examination showed the patient to be a well-nourished man of medium size, with tongue thickly coated, and slight pallor of the lips and mucous membranes. The temperature on admission was 102° F., the pulse was 104, and the respiration was 24. The thyroid gland was rather large, particularly the left lobe. Examination of the thorax and abdomen proved negative; the lungs were clear on auscultation and percussion; the cardiac area was normal. There was a soft systolic murmur over the heart, most marked in the pulmonary area, heard a short distance outwards into the axilla. The spleen was not palpable; there were no rose spots. There was great muscular tenderness and lameness. Light touches upon the skin and pinching of the skin caused no distress, while deeper pressure was followed by considerable pain, especially in the muscles of the arms, thighs, legs, and gluteal regions. There was no tenderness in the course of the long bones. The muscular tenderness was general. The patient lay quietly in bed, any voluntary motion being accompanied by considerable pain. The temperature remained continually elevated, for the first five days ranging between 100° and 104·3°. After March 8th the temperature began to fall gradually, reaching a point under 100° upon the 18th, after which it remained nearly normal. The urine was slightly reduced in quantity; there was a well-marked diazo reaction; the sediment contained a few granular casts. The blood, examined on March 6th, showed red blood corpuscles, 4,232,000; and leucocytes, 16,500. A differential count of the leucocytes[2] gave the following results: small mononuclear leucocytes, 5 per cent.; large mononuclear and transitional forms, 7 per cent.; polymorphonuclear neutrophiles, 50 per cent.; and eosinophiles, 38 per cent. Though the continued high temperature and general pains at first suggested typhoid fever, the absence of any abdominal symptoms, the leucocytosis, and the extraordinary increase in the eosinophilic cells rendered the diagnosis improbable. On the other hand, the extreme muscular tenderness on movements or on pressure pointed directly to a myositis, and a diagnosis of trichinosis was made. This was confirmed by the removal of a small piece of muscle from the right biceps on March 12th and the demonstration of active living trichinæ and others just beginning to be encapsulated. After March 18th the patient improved steadily and was discharged on May 13th well. About April 10th the patient first left his bed, and for some days afterwards there was slight œdema of the ankles, the only œdema which had at any time been noted during his illness. An examination of the blood was made daily by Dr. Brown during the patient's stay in the hospital, and the elaborate charts which he has prepared will appear shortly in his detailed studies upon the case. The total number of leucocytes per cubic millimetre ranged between about 13,000 on May 16th to over 35,000 on April 18th, being for the greater part of the time above 15,000 in number. The percentage of eosinophilic cells, which was 37 per cent. on the day of entry, fell to a little over 8 per cent. on March 22nd, and then rose gradually, reaching the extraordinary level of 68·2 per cent. on April 23rd. The small and large mononuclear elements remained throughout at a percentage slightly higher than one would have expected with the degree of leucocytosis existing—that is, at about their normal percentage or a little below this, while the number of polymorphonuclear neutrophiles was in directly inverse proportion to that of the eosinophiles. Thus on April 23rd, with a leucocytosis of 17,700, the differential count of the leucocytes was as follows: Small mononuclear leucocytes, 19·6 per cent.; large mononuclear and transitional forms, 5·2 per cent.; polymorphonuclear neutrophiles, 6·6 per cent.; and eosinophiles, 68·2 per cent.

CASE 2.—A German by birth, aged twenty-nine years, was admitted to the Johns Hopkins Hospital on April 15th, 1897, complaining of chills and fever, muscular pains, and weakness. The patient was a sailor, having recently arrived upon a steamer from Cuba. Several of his shipmates had during the trip developed intermittent malarial fever of the æstivo-autumnal type. Both his family history and personal history were negative. For about ten days or two weeks the patient had noticed a loss of appetite and general muscular weakness. Six days before admission he began to complain of continuous frontal headache, and for four days there had been considerable pain in the calves of the legs and in the back. For five days there had been slight general abdominal pain. On the morning of his admission to hospital the patient had two fluid stools. Five days before the patient had noticed a sudden œdema of the eyes and face. This was so marked that the eyes were opened with difficulty, the movements of the lids being accompanied by some pain. For several days he had had slight pain on mastication and on deep inspiration. There had been shaking chills and considerable fever. Physical examination showed the patient to be a well-nourished man. The lips and mucous membranes were of good colour; there was slight fulness of the eyelids, which, however, was not very marked, and the tongue had a pasty white coat. The lungs were clear throughout. With regard to the heart, the position and area of dulness were normal, and the sounds were clear and of normal relative intensity. The abdomen was natural in appearance. There was slight tenderness on pressure in the right iliac fossa. The spleen was just palpable. The border of the liver was to be felt on deep inspiration. There was no general glandular enlargement. There were a few small pinkish papules on the trunk suggestive of a typhoid roseola. The urine was reduced in

[1] Remarks made in the Section for Internal Medicine of the Twelfth International Medical Congress.

[2] Stained, according to Ehrlich's method, with the triple stain of acid fuchsin, methylene green, and orange green.

Digitized by Google

quantity, of a normal colour, and of specific gravity 1018; there was a slight trace of albumin; diazo reaction was not present, the sediment was slight, and there were no casts. As to the blood, the red corpuscles were 5,000,000 and the colourless corpuscles 13,000. A differential count of the leucocytes gave the following results: Small mononuclear forms, 11 per cent.; large mononuclear and transitional forms, 5 per cent.; polymorphonuclear neutrophiles, 37 per cent.; and eosinophiles, 44 per cent. Examination of the stools, which were fluid and of a deep brown colour, showed no mucus or blood, and there was no evidence of parasites or ova. The temperature pursued a remarkable course, daily elevations occurring at about noon, rising to a point as high as 105° F., and falling during the morning hours to a subnormal point. The paroxysms very closely resembled those of æstivo-autumnal malarial fever. Repeated examinations of the blood were made without showing the presence of parasites or pigment, and on April 18th I aspirated the spleen in order to exclude absolutely the presence of malarial infection. No pigment or parasites whatever were to be found in the splenic juice. Regular examinations of the blood were made by Dr. Brown with the following result. The number of leucocytes varied between 6000 on April 23rd and 13,000 on the 15th and May 3rd, while the percentage of eosinophiles varied between 14 per cent. on April 29th and 42·8 per cent. on the 15th. In this case, as in the former, the same inverse proportion existed between the number of neutrophilic and the eosinophilic leucocytes. Thus, on April 29th, with a leucocytosis of 12,000, there were only 14 per cent. of eosinophilic cells and 67 per cent. of polymorphonuclear neutrophiles, while on the 15th, with 42·8 per cent. of eosinophiles, there were 43·1 per cent. only of polymorphonuclear neutrophiles. It is extremely interesting that here the mononuclear forms represented almost exactly that percentage of the total number of leucocytes which might have been expected under ordinary circumstances, with a leucocytosis of the existing degree. The results, then, of blood examination were practically the same as those obtained in the above described case of trichinosis. The enormous percentage of eosinophilic cells present in the blood in connexion with our former experience led us to suspect the possibility of the existence of trichinosis in this instance, and consequently a small piece of muscle was removed from the calf of the right leg. Pieces of this muscle were examined in fresh salt solution without the discovery of trichinæ. The remaining bit of muscle was hardened in alcohol, embedded in paraffin, and cut. In the specimens stained in hæmatoxylin and eosin the characteristic degenerative processes described by Dr. Brown in the former case of trichinosis were discovered, and also in one portion of the muscle a characteristic young trichina embryo, not as yet encapsulated, which had evidently just entered into the muscle fibre. The patient made a good recovery, and left the hospital feeling perfectly well on May 18th, since which time he has escaped our observation.

Thus, in two instances of acute trichinosis we have discovered the remarkable fact that the blood contained a larger percentage of eosinophilic cells than has ever heretofore been noted. This increase in eosinophilic cells, so striking in the first instance, led us to suspect the existence of trichinosis in the second milder case in which the clinical symptoms would scarcely have justified a diagnosis. This observation we are inclined to believe may possess considerable diagnostic importance. It is important and interesting to note that this increase in eosinophilic cells occurred always in association with a leucocytosis, and that the increase in eosinophiles was invariably associated with a corresponding decrease in the polymorphonuclear neutrophilic elements. The small mononuclear elements and the large mononuclear and transitional forms preserved always either their normal proportion or a somewhat reduced percentage, as might have been suspected in connexion with a leucocytosis of the extent present; the percentage of the polynuclear and eosinophilic cells together form nearly or quite the proportion commonly represented by neutrophiles alone. These cells were always present in inverse proportion one to the other, an increase in the one variety being invariably associated with a decrease in the other. This remarkable fact points certainly to a close relationship between the origin of these two varieties of cells, and forms suggestive evidence in favour of the view held by some observers that the eosinophilic cells arise by some direct transformation from the ordinary polymorphonuclear neutrophilic elements. Dr. Brown suggests in an interesting manner that some such change may, in these instances, have taken place in the areas of degenerated muscle. Here he was able to demonstrate an enormous percentage of eosinophilic elements among the wandering cells, a percentage distinctly greater than that present in the circulating blood upon the same date or in the interfascicular vessels of the affected region. Dr. Brown also believes that he has demonstrated in the affected areas of the muscles transitional forms between the two varieties of cells—namely, polymorphonuclear elements possessing a granulation showing every stage between the small granules indefinitely staining with eosin—the ordinary neutrophilic granulation—to the well-marked, round or ovoid, refractive, deeply staining eosinophilic granules.

Conclusions.—1. In two instances of trichinosis the circulating blood has been found to contain a larger percentage of eosinophilic cells than has ever previously been demonstrated. 2. This increase in eosinophiles, occurring in connexion with a moderate or well-marked leucocytosis, always occurs at the expense of the polymorphonuclear neutrophilic elements, which are correspondingly diminished in number, the small and large mononuclear and transitional forms being present in normal proportions or in a percentage slightly below normal, not far from what one might expect with a leucocytosis of the existing degree. 3. Whether these changes in the blood are characteristic of trichinosis or whether they are also to be found in extensive myositis from other causes remains to be shown. 4. The remarkable inverse proportion between the eosinophiles and the neutrophiles in these instances, as well as the changes observed by Dr. Brown in the histological study of the muscle, form suggestive evidence in favour of the view that the increase in eosinophiles in these cases occurred by a direct transition from the polymorphonuclear neutrophilic elements.

Baltimore.

STRANGULATED HERNIA I NINFANCY WITH A REPORT OF A CASE OF INGUINAL HERNIA SUCCESSFULLY OPERATED UPON IN A CHILD AGED TWENTY-TWO DAYS.

BY BERKELEY G. A. MOYNIHAN, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON, LEEDS GENERAL INFIRMARY.

STRANGULATED hernia requiring operation during infancy is a very unusual occurrence. The most recent contributions to the literature of the subject have been published by Carl Stern[1] and by Tariel[2] of Paris. The extreme rarity of the condition is forcibly insisted upon by both writers. Stern, in order to determine its frequency, consulted the records of the children's hospitals of Basle, Prague, Breslau, Vienna, Krakow, Frankfort, Amsterdam, Berne, and Göttingen. In these hospitals for four consecutive years 139,000 children were treated, but there is no record of any case of herniotomy for strangulation. Of 1900 cases operated upon for strangulated hernia in various hospitals 13 occurred in children. The proportion of cases in adults as compared with children is calculated by Stern to be in the ratio approximately of 108 to 1. Tariel, after remarking that several noted surgeons, among whom are Holmes, Gosselin, St. Germain, and Lannelongue, have never met with acute cases requiring herniotomy, tabulates the records that he has been able to collect. They number in all 128. König states that throughout his long surgical career he has only met with two cases requiring operation in the "early years" of childhood. Nussbaum operated upon two cases among a total number of 54,000 children under his care. Broca found strangulation in 9 cases out of 200 requiring radical cure in infancy. The first collection of records of operations of this kind was made by Ravoth, who tabulated 30 well authenticated cases. Féré, who followed him, investigated the records of 52 operations in 56 cases. Howard Marsh,[3] in 1874, collected 47 cases. Knobloch,

whose investigations preceded those of Stern, compiled notes of 87 herniotomies for inguinal, 11 for umbilical, and 1 for femoral hernia. To this already comprehensive list Stern added 51 later cases of inguinal and 3 of umbilical hernia.

On a perusal of these researches two facts stand prominenently out from the point of view of interest. The first is that operations are more frequently called for during the earlier months of childhood than during the later. The greatest number occur in the first, second, and third months of the first year. The proportion after this period diminishes very rapidly as is shown by comparing in a tabular form the cases operated upon in each of the first twelve months.

During the	1st	month	16	cases	occurred.
,,	2nd	,,	15	,,	,,
,,	3rd	,,	14	,,	,,
,,	4th	,,	9	,,	,,

,,	10th	,,	3	,,	,,
,,	11th	,,	3	,,	,,
,,	12th	,,	4	,,	,,

During the third and fourth years only 4 cases are noted. The second point is this—that the symptom most commonly observed in children, or perhaps one should call it an associated condition rather than a symptom proper, is retention of urine.

With regard to the cause of strangulation Howard Marsh states that, in 32 cases which he investigated, in 20 it was in the neck of the sac, in 7 at the external ring, in 3 at the internal ring, in 1 at both rings, and at the conjoined tendon in 1. Tariel found that the neck of the sac caused the constriction in 58 cases out of a total of 81 examined. The contents are most frequently portions of the small intestine, but in a proportion not inconsiderable the cæcum and the appendix have been found within the sac. In one case the Fallopian tube and ovary were present.

The treatment of strangulated hernia in infancy does not differ from the similar condition found in adults. A radical cure should always be performed if the condition of the patient permits it. Both Stern and Tariel compute the mortality of the operation, but as the cases they investigated extended over a period of nearly thirty years no great reliance can be placed on the percentage of deaths. One fact, however, seems quite clear—that the mortality during the first four years of life is quite appreciably less than the average mortality of later years. The last short series of cases deserving of mention are those of Coley,[4] of New York. He operated upon five cases in infants under one year. Death occurred in a child practically moribund at the beginning of the operation. In two cases the cæcum and appendix were found in the sac. A radical cure was performed in all cases. Up to the present none have relapsed.

The following case has recently come under my care. The patient was a male, aged twenty-two days. Since birth a rupture had been noticed on the right side. About twenty-four hours before I saw him the rupture came down when the child was crying. The mother, on examining it, found that the size of the swelling was larger than she had previously noticed it, and her attempts at reduction failed. Within an hour the child had vomited and had continued to do so at intervals which were becoming gradually curtailed. For about twelve hours no urine had passed. On examination I found a tense inguinal hernia on the right side, of approximately the size of a billiard ball. Attempts were made to reduce the hernia without, and with, anæsthesia from chloroform, but were unsuccessful. I at once proceeded to operate. The sac of what I saw to be a congenital hernia contained a little fluid, and about ten or twelve inches of distended and discoloured small intestine. The point of strangulation was at the neck of the sac. I stretched the rings with my finger and returned the gut; completing the operation by performing a radical cure by Ball's method and by fashioning a tunica vaginalis from the lower part of the sac. A dressing of collodion and gauze was applied. During the operation the child passed urine. The after history was uneventful and recovery was speedy. Up to the present the hernia has not returned; no truss is worn.

THE NON-CONTAGIOUSNESS OF ANÆSTHETIC LEPROSY.

By S. P. IMPEY,

LATE MEDICAL SUPERINTENDENT, ROBBEN ISLAND, CAPE COLONY.

I THINK all medical men who have paid attention to the study of leprosy are agreed that the disease is due to the presence in the system of the bacillus lepræ, the true nature of which was discovered by Dr. Amauer Hansen of Bergen. This bacillus is a difficult one to study, for it has not only not been discovered in any other tissues but that of the human body, but it has defied all attempts at cultivating it in artificial media, and all inoculation experiments with it on the lower animals have failed, so that its life-history is not well known; but, nevertheless, we have during the last few years added much to our knowledge concerning the disease of which it is the cause. If the bacillus is the cause of leprosy, and it is found only in the human body, it follows that the human body must be the source of infection of all fresh cases of leprosy, and it also follows that in order to stamp out the disease or to check its spread the diseased must be separated from the healthy.

I had, whilst on Robben Island, a large number of lepers under my charge, who afforded me a good opportunity of becoming well acquainted with the disease and its treatment, and I spent much time and devoted much attention to the study of the prophylactic treatment of the disease. The more I studied the subject, and the more I became acquainted with the true nature of leprosy, the more I became convinced that the systems of segregation adopted in this and other countries were wrong—wrong in principle, wrong in practice, and wholly unscientific. I found that the laws dealing with the lepers, which were made at a time when the disease was not understood, were not only inadequate, but, by their very severity, were retarding the work for which they were framed. I became convinced that if leprosy was to be stamped out effectually a simpler and less harsh system of segregation should be adopted—a system based upon the solid foundation of knowledge, and one that was scientifically correct. I am a firm believer in the efficacy of segregation, for I think that the only way in which we can hope to check the spread of leprosy is by isolating those cases which are a danger to the public, but I also believe that it is unnecessary to isolate all lepers, for though some lepers are undoubtedly highly dangerous to the public, others are, in my opinion, harmless. I think the dangerous cases should be very strictly segregated, but the harmless lepers should be allowed their liberty. My object in writing this paper is to endeavour to show that all cases of anæsthetic leprosy are harmless, and that it is not only unnecessary but wrong to force them to live in leper asylums.

Patients suffering from leprosy may, for all practical purposes, be divided into two classes, those in whom nodules or tubercles occur and those in whom there are no tubercles. The former class includes all tuberculous and mixed cases, the latter all cases of anæsthetic or nerve leprosy. In tuberculous and mixed leprosy bacilli are found in many tissues of the body, in anæsthetic leprosy they are confined to the nerves. I am aware that some authorities are of opinion that the bacilli are found in the cutis in the anæsthetic patches, especially during the erythematous stage of the disease, but this I think is a mistake. Professor Unna, of Hamburg, and others are of opinion that in anæsthetic leprosy all the tissues of the body except the nerves are immune against the bacilli; with this opinion I entirely agree, for if it were not so nodules would form in all cases and bacilli would be found in some other of the tissues, but I have never been able to find the bacilli in the body of an anæsthetic leper except in the nerves. We must, therefore, conclude that the cutis and other parts in anæsthetic leprosy are protected in some way against the leper bacillus, and that the bacilli cannot exist elsewhere than in the nerves. I am of opinion that those who have reported the finding of bacilli in the cutis of anæsthetic leprosy have made an error of diagnosis and have mistaken mixed or tuberculous leprosy for the anæsthetic form of the disease. During the erythematous stage of leprosy the two forms are very much alike, so that unless the greatest care is taken an error of diagnosis may be very easily made

Digitized by Google

even by one well acquainted with the disease. All things go to show that there is very little doubt that in anæsthetic leprosy the bacilli are confined to the nerves. All the nerves of the body are not attacked by the bacilli, nor are the affected nerves diseased in the whole of their extent; the bacilli are found only in certain nerves and in certain parts of those nerves. They are found in the nerves of the extremities, in some of the cutaneous nerves of the trunk, and in some of the nerves supplying the facial muscles. The bacilli are thus limited in their distribution, but, what is of perhaps greater importance, they are limited as to the time of their stay in the body. The bacilli enter the nerves and there set up a violent form of neuritis which soon destroys the nerve fibres; in the general destruction the bacilli are themselves killed. All the fibres in a nerve may be destroyed or some of them only, and the amount of tissue destruction is wholly dependent upon the amount of nerve destruction. The parts which are deprived of their nerve power are lowered in vitality, and thus become the seat of much tissue destruction. It may be readily seen that the more central the lesion in the nerves is, the greater is the resulting tissue destruction, and the more peripheral the seat of lesion in the nerve the less will the tissues be destroyed. This is only what we might expect from the nature of the pathology of anæsthetic leprosy, but these circumstances or results play an important part in determining whether anæsthetic lepropsy is contagious or not. If only the terminal twigs of a nerve are diseased there is little harm done; there is some anæsthesia of the parts and there may be some atrophy of the tissues, but there is no ulceration. The anæsthetic patches on the body of a leper are instances of this form of lesion; they never become ulcerated. If the nerves are diseased in the neighbourhood of the wrist-joint there is generally only a slight numbness of the fingers, with, perhaps, a slight contraction of the digits, but there is no ulceration. If the nerve lesion is in the neighbourhood of the elbow-joint—the most usual site—and all the fibres of the nerves are affected, then we find ulceration and destruction of the fingers with loss often of the metacarpal bones. If the lesion is still more central we may have destruction or absorption of the bones of the forearm up to within a short distance of the elbow-joint; this, however, is an exceedingly rare occurrence. In an anæsthetic patch the bacilli are confined to the nerves and there is no broken surface, so that it is highly improbable, and I may say almost impossible, that the bacilli can escape from one of the patches. The bacilli also are found in these patches only during the erythematous stage of the disease, which is of comparatively short duration, for coincident with the subsidence of the congestion is the disappearance of the bacilli from the part, so that all that remains of a colony of bacilli in an old anæsthetic patch is a mass of granules, composed of disintegrated micro-organisms, embedded in the fibrous band which is all that remains of the diseased nerve. In consideration of these facts I think it may therefore be conceded that the leper bacilli do not escape from the anæsthetic patches. With regard, however, to the more serious changes which take place in the extremities, there are certainly many wounds, but nevertheless the bacilli cannot leave the body by them. If the nerve is diseased in the neighbourhood of the wrist joint no wounds are found, so that the bacilli cannot escape. If the nerve is diseased at the elbow joint there are wounds on the fingers or in the hand, but here the bacilli are far removed from the broken surface, and therefore they are not likely to escape by it, nor, in fact, do they escape by these wounds. I have never yet detected a bacillus in the discharges from wounds of an anæsthetic leper, nor have I met a leprologist who has done so, so that though there are many wounds in an anæsthetic leper's body, yet it must be acknowledged that the bacilli do not leave the body by these wounds.

Now we know that in anæsthetic leprosy the bacilli are, and must be, confined to the nerves, for, as I have before mentioned, all the other tissues of the body are immune against the bacilli, therefore they cannot attack the internal organs or exist in the lymphatic and other glands of the body. The bacilli are confined to the nerves, and I have shown why they cannot escape from the nerves, therefore I think all must acknowledge that though leprosy is theoretically a contagious disease, yet the anæsthetic form of it is practically non-contagious, and therefore perfectly harmless. But there is yet another reason why most anæsthetic lepers are harmless. Some years ago I expressed the opinion that some cases of anæsthetic leprosy became self-cured, meaning thereby that in these cases the bacilli had ceased to exist in the nerves, that this fortunate condition was due to natural causes and not to medical treatment, that, in fact, the disease had run its course and had thus cured itself. I further stated that it was only in the earlier stages of anæsthetic leprosy that it was possible to find the bacilli in the nerves, and that in the later stages all traces of the bacilli were lost. These opinions are now recognised as correct by, I think, all those who have studied the subject. Nearly all diseases caused by bacilli have a definite course to run, after which the tissues become immunised and the bacilli die, and leprosy is no exception to the rule, only, unfortunately, the disease is such a severe one that few patients live long enough to tell the tale.

It is difficult to fix the exact date when the bacilli cease to exist in the body of an anæsthetic leper; I did think it was at about the tenth year, but I have reason now to believe that the disease is of much shorter duration, and that four years is much nearer the mark. The duration of anæsthetic leprosy is generally put down as from five to forty years, or even more, but this is wrong, and the mistake is due to the fact that the results of the disease are taken for the disease itself. We might just as well say that the duration of small-pox is from three weeks to ninety years, for many people who die at this ripe old age are pitted by the disease. If leprosy is due to the bacilli, which no one now denies, then surely when the bacilli cease to live in the body the disease itself must cease to exist, and the patient after that suffers from the effects of the disease and not from the disease itself. That the bacillus lepræ does cease to exist in the body which it has more or less destroyed is proved by the fact that no bacilli can be found in the body of a chronic case. Such patients are cured, and we have no more reason to call them lepers or to say that they are suffering from the disease than we have to say that because a man is marked by small-pox he is suffering from variola. I think it is not only unnecessary to isolate these cured cases, but I think it is wrong to force them to herd with those who are a constant and distinct danger to those about them.

It has been stated that in advanced cases of anæsthetic leprosy—cases in which the disease has been apparently dormant for years—there have been fresh outbreaks of the disease, and that in some of these cases nodules develop. I do not deny this statement, for I have seen similar cases, but I do not agree as to the assigned cause of the fresh outbreak. I cannot believe that the bacillus remains dormant for so many years and then without rhyme or reason starts to work again; but I do believe that these fresh outbreaks are due to re-infection. It is an unusual occurrence to have a fresh outbreak, but when it does occur after many years it most invariably takes on the nodular form of the disease, which goes to prove, I think, that it is a case of re-infection and not of recrudescence.

In an anæsthetic leper most of the tissues are protected against the bacillus, but we know that immunity seldom is of very long duration, so that we can readily conceive that when the bacillus ceases to exist in the body its antitoxin effects would pass off, leaving the tissues unprotected against a second attack of the disease. Many of the cured cases, though free from bacilli, have many wounds, and being thus forced to live in close and constant contact with the nodular cases, from whose bodies there is a plentiful supply of bacilli constantly escaping, it is not to be wondered at that there are cases of re-infection; the wonder it that any of them escape.

The question of the non-contagiousness of anæsthetic leprosy is not only a most interesting one, but one that deserves the earnest attention of the medical profession, for upon the correctness or not of my opinion depends in a great measure the future treatment of the leprosy question. One of the greatest medical problems of the day is—How best to deal with the lepers in order to check the spread of a disease which has of late years made vast strides and rapid progress in almost every part of the world. The whole question resolves itself into a matter of "£ *s. d.*" Many countries have not attempted segregation on account of the expense, for in many cases the number of lepers is so great that the finances of the country cannot stand the cost of providing hospital accommodation for them all. Other countries for the same reason have adopted a system of partial segregation with most unsatisfactory results; in no country is complete segregation insisted upon. In South Africa half the lepers

Digitized by Google

are at the present time at large because there is no room for all in the asylums. In warm countries there are twice as many anæsthetic lepers as there are nodular ones, so that if it is found unnecessary to segregate the anæsthetic cases the number of lepers to be dealt with is at once enormously reduced, and the cost of stamping out the disease will be reduced to the extent of two-thirds of what is at present required.

I am of opinion that in the Cape Colony, with half the present accommodation at my disposal, I could find room for every leper who is a danger to the public. At the present time the asylum wards are crowded with patients, many of whom are cured anæsthetic cases, and who are therefore harmless, to the exclusion of a large number of nodular cases, who are a distinct danger to the healthy public, and who, being at large, are daily spreading the disease. We are, by thus dealing with all lepers indiscriminately, not only inflicting an unnecessary hardship upon many whose sufferings are already almost beyond endurance, but we are actually retarding the work on account of which we are making the innocent suffer. I think all anæsthetic lepers should at once be removed from the leper asylums, and if they cannot support themselves they should be treated as ordinary paupers. By allowing the present system of indiscriminate segregation to continue the legislators are forcing the unfortunate anæsthetic cases to expose themselves to the danger of re-infection and of contracting a disease which it is our endeavour to stamp out.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

TOXIC SWEAT AND ITS VICARIOUS ELIMINATION.

BY DAVID WALSH, M.D. EDIN.,
PHYSICIAN TO THE WESTERN SKIN HOSPITAL.

THE toxic nature of the ordinary sweat of man appears to be well established by the researches of M. Arloing recently published in translated form in the columns of THE LANCET.[1] If confirmed, his observation is likely to throw light upon a number of more or less obscure problems both of etiology and of pathology. If it be true that the skin habitually excretes a toxic substance or substances, then it follows that if the sweat be checked—e.g., by a chill—the toxic material will accumulate in the blood, and the stress of its excretion will be thrown upon other organs. This toxic sudorific material, assuming it to exist, does not appear to damage the skin in normal perspiration, but when the action of the skin is suddenly excited, as by a Turkish bath, there sometimes results an immediate and very definite papular rash which has a strong analogy with the "prickly heat" of the tropics. Perhaps the explanation of this interesting phenomenon may be found in the increased amount of irritant toxic material brought to the skin. That effect might obviously be intensified by the presence of other irritants existing in the blood, such as certain drugs or specific poisons, which are, as it were, superadded to the ordinary toxic principles of sweat.

The general relationship of skin rashes to inflammation of other eliminating organs I have discussed elsewhere.[2] Briefly put, this theory of excretory irritation suggests that a large class of skin rashes are the direct result of the excretion of some irritant from the blood. The irritant may be in the form either of a drug (as arsenic), of a specific micro-organism or its products (exanthems or antitoxin), or of other poisons introduced from without or elaborated within the body (ptomaine poisoning or gout). All, or nearly all, internal agents that cause a dermatitis are capable of inflaming other channels of exit of waste from the body, as the lungs, kidneys, or bowel. In this way arsenic may set up dermatitis, gastro-enteritis, and nephritis, and scarlet fever (presumably due to specific microbes) may give rise to a similar train of evils. In other words, a blood borne irritant agent that is capable of inflaming the skin may also attack vicarious routes of excretion. The time-worn illustration of a knot of persons exposed to some common injurious condition of environment, but who suffer therefrom in different ways, is familiar enough to medical readers. Four men, say, are immersed in a stream; as a result one develops coryza, a second pneumonia, a third nephritis, and a fourth rheumatism. Let it now be supposed that four men suffer in those various ways after exposure to a draught of cool air while sweating freely. Let it also be assumed that sweat normally contains, as M. Arloing asserts,[3] "some energetically poisonous substances, occasioning more or less derangement to all parts of the organism, disturbing the intimate phenomena of nutrition, modifying the composition of the blood, substances the properties of which possess a strong analogy to certain microbic toxins." The sudden suppression of the sweat is likely to force these "normal" toxic materials back upon the blood, and the stress of their elimination must then necessarily fall upon other eliminatory organs, with such possible or probable results as nephritis, pneumonia, and other excretory inflammations. But there is more than this. In rheumatism the blood in the first instance is probably always more or less at fault, and there is no evidence to show that in the rheumatic condition the toxic principle of the sweat is not much more complex in composition and variable in effect. If such were the case the result of damming its skin exit, and thus inviting vicarious elimination, would be *pari passu* a much more serious matter—that is to say, there would be infinitely more risk in checking a pathological than a normal sweat. It will be most interesting to learn if M. Arloing has extended his experiments to the relative toxicity of normal and pathological sweats, the latter to include the skin excretions of various fevers, rheumatism, gout, septicæmia, and so on. From the constant association of "chills" and arrested sweating with rheumatism one is tempted to hope that the brilliant researches of M. Arloing may give some clue to the etiology of a disease in which so much remains to be discovered. One is the more hopeful of such an issue upon recalling the striking analogy between the signs and symptoms of many of the septic poisonings and those of rheumatism.

Endless problems are suggested by even a superficial consideration of this captivating theory of the toxicity of sweat. Why, for instance, is exposure to cold so extremely dangerous when a patient has developed the rash of scarlet fever? It is known from clinical experience that the sudden disappearance of the rash is usually a sign of grave import, and that chill spells nephritis. May it not be that the action of the skin is checked while actively engaged in excreting toxic irritant substances, the elimination of which is then thrown upon the kidneys and other organs? That is to say, the excretory irritation is shifted from the skin to the kidneys. Moreover, it appears not altogether unlikely that a checked skin elimination might be the cause of the subacute rheumatism that often follows scarlet fever. It seems curious in these days of accumulated knowledge that there should be no established scientific explanation of the cause and relations of so everyday a phenomenon as the rash of scarlet fever.

TWO CASES OF PUERPERAL SEPTICÆMIA TREATED BY ANTI-STREPTOCOCCIC SERUM; RECOVERY.

BY RICHARD RICHMOND, M.D. EDIN.

THE results obtained by the serum treatment in the two following cases have led me to think that the few notes taken during their progress may be of some interest to the profession.

CASE 1.—This patient was delivered naturally and easily of her third child on May 24th, 1897, and remained well until the 26th, when she had a "shivering fit." On the 27th her temperature was 102·2° F., her pulse was 115, and she was in great discomfort, with headache and a hot, dry skin. Her tongue was covered with a thick yellowish fur; the lochial discharge was very scanty, pale, and somewhat fetid, but not particularly offensive, and

[3] THE LANCET, Sept. 11th, 1897, p. 677.

Digitized by Google

there was considerable tenderness on pressure over the uterus. She was given three grains of calomel at bedtime and five grains of sulphate of quinine every four hours. On the 28th the temperature was 101° and the pulse 106. The patient's bowels acted freely and she expressed herself as feeling better; but the tenderness over the uterus was very marked, the lochia were scanty, and the secretion of milk was almost *nil*. The quinine was continued, and the calomel was repeated at bedtime. On the 29th the temperature was 100° and the pulse 100. The patient was still very ill, her tongue was thickly coated, and she was unable to take food; there was no change in the lochia. On the 30th the temperature was 101·6° and the pulse 110. There was no improvement in the symptoms, and 10 c.c. of anti-streptococcic serum were injected under the skin of the abdomen, the quinine being also stopped. On the 31st the temperature was 98·4°, the pulse was 72, and the change in the patient was remarkable. She expressed herself as being well. She slept eight and a half hours during the night, her skin was moist and cool, and her tongue commenced to clean; the lochial discharge was somewhat increased in amount; 5 c.c. of serum were injected. On June 1st the temperature was 98·2° and the pulse 74. The patient was much better, and she asked to be allowed to sit up in bed; 5 c.c. of serum were injected. On the 2nd the temperature was 98·2°, and the pulse 66; the tenderness over the uterus was quite gone, the lochia were natural in amount, and milk was freely secreted. The further progress of the case was perfectly satisfactory.

CASE 2.—This patient was a primipara who was attacked by puerperal septicæmia followed by pelvic cellulitis. At her confinement, which occurred on May 29th, 1897 the presented; the delivery of the head was difficult, the breech perineum was lacerated, and there was somewhat severe post-partum hæmorrhage. The patient had been confined to bed with rheumatism for two months previous to delivery. During the first few days after delivery her temperature remained normal, though her pulse-rate varied from 100 to 110. On June 3rd she had a slight rigor; her temperature rose to 101·8° and her pulse to 140. The lochial discharges were plentiful, but pale in colour and very offensive. The vagina was douched with perchloride of mercury (1 in 2000), and four grains of quinine sulphate were given every four hours. On the 4th the temperature was 101·2° and the pulse 130; there was some tenderness over the uterus and the secretion of milk was in abeyance; 8 c.c. of anti-streptococcic serum were injected into the abdominal wall. On the 5th the temperature was 99·4° and the pulse was 120. There was distinct improvement in the lochia and milk was secreted in small amount; the vaginal douches were continued; the perineal laceration looked healthy, but was not healed; 5 c.c. of serum were injected. On the 6th the temperature was 99·4° and the pulse 122; serum was injected in the same quantity as the day before. On the 7th the temperature was 98·2° and the pulse 120. The patient's general condition was satisfactory, but she was anæmic and weak; she, however, took her food well; the lochia were apparently natural, and no serum was used. On the 8th the temperature was 98·4° and the pulse 120; during the night there was profuse lochial discharge of a ruddy colour. On the 9th the temperature rose to 104° and the pulse to 140, the lochia became offensive, and there was great tenderness over the lower part of the abdomen. The uterus was douched with perchloride of mercury solution (1 in 4000), 10 c.c. of serum were injected, and hot fomentations were applied over the abdomen. On the 10th the temperature was 100° and the pulse 125; 5 c.c. of serum were injected. On the 11th the temperature was 100·4° and the pulse 124; the uterus was douched. On the 12th I left home for a holiday and Mr. W. F. Blewitt, my locum tenens, took charge of the case. According to his notes there was a rise of temperature on that day to 102° and then for the next ten days it remained about 100°. On my advice he continued small injections of serum daily for a week. Further progress was slow but uneventful. Mr. Blewitt noticed considerable exudation to the left of the uterus on June 18th.

Remarks.—In the first case the rapid and complete recovery which followed the first injection of serum need not be dwelt upon; no other treatment whatever was used after the serum was injected. In the second case the temperature did not become normal until after the third injection. Had the injections of serum been continued instead of being stopped on June 7th I believe the trouble which followed might have been avoided. The first patient became infected by the nurse, who, I afterwards discovered, had an offensive vaginal discharge. It is not so easy to account for the infection of the second case. If I was the means of conveying infection from Case 1 it was not due to want of care on my part, as I took great pains to render my hands (and person as far as possible) aseptic. The serum was supplied by the British Institute of Preventive Medicine.

Great Bardfield.

CASE OF ATTEMPTED POISONING BY TINCTURE OF OPIUM AND ANTIPYRIN; RECOVERY.

BY W. HERBERT GREGORY, M.D. EDIN.

ON July 18th last I was hurriedly summoned to attend a woman who had, while in a depressed state, taken overdoses of laudanum and antipyrin. On arriving at 5 A.M. I found her in an excited state, but she answered all my queries readily and distinctly. The temperature was 99° F., the pulse was 100, and the pupils were perfectly normal and contracted to light. By the patient's own statements, the evidence of her husband, and the bottles which contained the drug (now in my possession), I found that at 9.30 A.M. the day before (July 17th) she had taken eighteen drachms of tincture of opium, and at 10.30 P.M. on the same day from 60 to 70 grains of antipyrin. These drugs had been procured for toothache from several different druggists. Shortly before I arrived she had been slightly sick, but the vomit had been thrown away. I washed out the stomach and found that what came away smelled most strongly of laudanum. The recovery was perfect except for a slight amount of dyspepsia for a few days afterwards.

Into the cause which induced the attempt at suicide it is unnecessary to enter here. The important point is that there never had been any opium habit, and there is also no doubt whatever that both drugs were taken in the amounts stated. The curious point about the case is the long retention of the laudanum in the stomach without any marked symptoms. The only noticeable symptom was a slight unsteadiness of gait in walking across the floor on the afternoon of the 17th. This, the patient assured her husband, was due to her being "bilious." From 9.30 A.M. on the 17th to 5 A.M. on the 18th is nineteen and a half hours, and this, combined with the circumstance that antipyrin in a 60- or 70-grain dose (a dose highly depressant to the heart) was also taken without effect, makes the case almost an unique one. Cases are on record where opium has been retained in the stomach for nine, ten, and even eighteen hours, and in THE LANCET of July 15th, 1857, Dr. Gibbs published a case where 12 drachms of laudanum had been rejected spontaneously from the stomach after a lapse of nine hours without giving rise to any marked symptoms.

I am not aware that antipyrin is in any way an antidote to opium—at least, I have not seen it mentioned in the books; but, even allowing that it were, there was an interval of thirteen hours between the times of taking the two drugs. The case appears to me to be of interest, and I cite it to show that opium may be retained for hours in the stomach without giving rise to any noticeable symptoms.

Beverley.

THE EXTENSION OF THE BRISTOL BOUNDARIES.—On Nov. 1st, when the Bristol Boundaries Extension Act comes into operation, the population of Bristol, it is estimated, will be 317,833 and the acreage 11,397. The effect of the Act will cause a consolidation of authority, which means one council, one school board, and one board of guardians, instead of eighteen different authorities which existed before the passing of the Act.

EXPENDITURE AT THE CARDIFF INFIRMARY.—For some time past reports have gone abroad that the Cardiff Infirmary was managed upon very extravagant principles. We are glad to find, however, that from inquiries which have been made it appears that the average cost per bed on total expenditure is at Cardiff £50 1*s.* 4½*d.*, while at thirty-four similar institutions throughout the country it is £64 12*s.* 2½*d.* Thus there is a balance in favour of Cardiff of £14 10*s.* 10½*d.* Unfortunately, up to the present date donations have fallen off by £600 and the revenue from outdoor nursing has also decreased.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. BARTHOLOMEW'S HOSPITAL.

A CASE OF STRANGULATED PARTIAL ENTEROCELE OF THE CÆCUM WITHOUT SYMPTOMS; FÆCAL FISTULA; RESECTION OF PART OF THE CÆCUM; RECOVERY.

(Under the care of Mr. ANTHONY BOWLBY.)

THE presence or absence of symptoms in constricted partial enteroceles seems to depend chiefly on the proportion of the circumference of the bowel which is included within the constriction. In the following case the portion of the bowel wall which entered the crural canal seems to have been only a small part of the circumference of the cæcum, so that its constriction had no influence on the functional activity of the intestine. The case was one eminently suitable for the treatment adopted, as the operation did not necessitate any interference with the continuity of the bowel. The perfectly aseptic course of the case shows how thoroughly a septic fæcal fistula can be disinfected.

A married woman, aged forty-six years, was admitted to Stanley Ward, St. Bartholomew's Hospital, on Nov. 7th, 1896, with a fæcal fistula in the right groin. For two years she had noticed a swelling of the size of a walnut in the right femoral region. The swelling was always more or less tender, and sometimes caused her considerable pain. She thought that it was always present, never disappearing, even at night time. Three months prior to her admission to the hospital the swelling suddenly increased in size, becoming about four inches long and two inches broad. It lay with its long axis parallel to Poupart's ligament, and was oval in shape. The skin over it became red and extremely tender. She noticed no unusual constipation at this time, but she was once sick. The application of hot flannels was the only treatment adopted. Three or four days later the swelling burst spontaneously, and discharged a stinking watery fluid of a yellowish colour. The patient felt much relieved by the bursting of the swelling. The discharge from the wound continued, and one month before admission she for the first time noticed a fæcal smell and some fæcal matter in the discharge. This was immediately preceded by some blood-stained discharge. During the three weeks which preceded her admission to the hospital she remained in fairly good health, and passed on an average three motions a week by the wound. The bowels were all this time regularly opened in the usual manner. She stated that she had always been a healthy woman and had never had any serious illness, with the exception of scarlet fever during her childhood. She had never had typhoid fever. She had suffered all her life from "wind" and constipation. On admission to the hospital she presented a fairly healthy appearance. In the right groin there was a sinus discharging thick fæces and a little pus. The opening of the sinus was one inch external to and below the pubic spine. The abdominal wall was extremely lax, and the moving coils of intestine could be readily seen. The urine was normal. On Nov. 20th the sinus was explored under an anæsthetic. The external opening was enlarged. A probe was passed upwards and to the right, and seemed to go straight into the lumen of the intestine. The sinus obviously traversed the crural canal. The walls of the sinus were well scraped and the cavity packed with iodoform gauze. This treatment produced practically no change in the condition of the fistula, which still discharged fæcal matter at irregular intervals. The bowels were opened per rectum by means of aperients and enemata. On one occasion the injection of a large enema was thought to produce an immediate increase of fæcal discharge from the fistula. On Dec. 4th the patient was shown at the weekly surgical consultations. It was suggested that the solid character of the fæces discharged from the fistula pointed to the large intestine being the part involved, and the opinion was expressed that as the discharge was certainly passing out through the crural canal, it was probably a case of strangulated hernia. As no improvement had resulted from laying open the sinus and packing its walls an operation through the peritoneal cavity was advised, and it was suggested that either an ulcerated aperture might be sutured, or that, if the cæcum showed evidence of tuberculous disease, it might be excised. The opinions of all those who saw the patient were unanimous in favour of the proposed course. On the 11th an anæsthetic was administered. The skin of the abdomen having been thoroughly cleaned the abdomen was opened by a vertical incision over the cæcum, its lower end being about three-quarters of an inch above the opening of the fistula. The small intestines having been pushed aside with a flat sponge, and the peritoneal cavity being protected by other sponges, the cæcum was drawn into the wound, and it was then seen that the fistula led into its lowest part, at a point just external to the base of the vermiform appendix. This part of the cæcum had been dragged down so as to form a pouch, and the latter was now carefully dissected away from its attachments in the crural ring and cut away from the cæcum, an opening being thus made in the cæcum about one and a half inches in length. The vermiform appendix seemed perfectly normal, but owing to the proximity of its base to the line of suture it was thought advisable to remove it. The opening in the cæcum was then closed by a continuous suture of its mucous membrane, and two rows of interrupted Lembert's sutures. The track through the crural canal previously occupied by the hernial pouch was thoroughly cleaned with perchloride lotion and the small piece of adherent intestine was dissected away. The mouth of the fistula in the groin was swabbed finally with pure carbolic acid. The peritoneal cavity was closed with silk sutures, two gauze drains being inserted, one in the lower angle of the incision, and one through the crural canal. The muscular walls and skin were sutured separately with silk-worm gut. The patient was afterwards a little sick during the first few hours, but stood the operation well. On the 12th the gauze drain was removed from the upper wound. Both wounds looked perfectly dry and healthy. There was no redness of the skin. The temperature had never been higher than 99·2° F. The patient seemed perfectly comfortable and complained of no pain. On the 17th the second gauze drain was removed. The bowels were opened for the first time since the operation with an enema. On the 24th all the stitches were removed. The upper wound was entirely healed. There was a shallow granulating ulcer in the situation of the lower wound. On Jan. 25th, 1897, the bowels were opened for the second time with an enema. On Feb. 13th the patient left the hospital, wearing an abdominal belt, with both wounds soundly healed. The feeding of the patient during the first four days was entirely by rectal enemata with the exception of very small quantities of water by the mouth. For the next week very little food was taken by the stomach, and such as was taken was calculated to leave but little residue in the intestine.

Remarks by Mr. BOWLBY.—Cases of strangulation of the cæcum alone without the involvement of any small intestine are rare, but in such cases as have come to my knowledge it seems that the symptoms of strangulation were well marked. In the present case there was but little of the cæcum strangulated, and there does not appear to have been any material colic or sickness in spite of the constriction of the whole thickness of the wall of the bowel where it was completely covered by peritoneum. There is but little to say of the operation itself, but it may be pointed out that the risk of resection of bowel and enterorrhaphy in such a case is mainly due to the presence of a septic sinus which at the time of operation has necessarily to be opened so as to communicate with the peritoneal cavity. It was by the resection of all the infected tissue, the disinfection of the sinus opening, and the subsequent packing with iodoform gauze that the peritoneum was efficiently protected. I am much indebted to my friend Mr. Lockwood for his kind assistance at the operation, and to my house surgeon, Dr. Meakin, for the notes of the case.

NORTH STAFFORDSHIRE INFIRMARY.

A CASE OF RUPTURE OF THE TRACHEA; NECROPSY.

(Under the care of Mr. J. ALCOCK.)

THE comparative immunity from injury enjoyed by the trachea is probably to be attributed in part to the great elasticity conferred on it by the presence of the cartilaginous

Digitized by Google

arches in its wall and in part to its mobility. As there was in the following case from the injury itself great probability of a septic infection of the tissues surrounding the trachea, an external opening would have added but little to the danger, yet the great amount of separation of the ends of the trachea must have rendered extremely difficult any attempt to suture them. The diagnosis, though extremely doubtful on account of the subcutaneous emphysema, was to some extent possible, as the very presence of air in the tissues showed that the air passages had been wounded. A laryngoscopic examination might have afforded some information. For the notes of the case we are indebted to Mr. A. S. Barling, late house surgeon at the North Staffordshire Infirmary, and now surgeon to the Royal Lancaster Infirmary.

The patient, a man aged twenty-four years, was admitted to the infirmary, under the care of Mr. Alcock, on April 20th, 1892, suffering from an injury to the chest and neck. About two hours before admission he was engaged in lowering heavy balks of timber by means of a crane, when one of the iron supports gave way. The man saw the beam of the crane falling on him, and threw his head back to avoid it, Just at this moment—i.e., when the neck was fully extended and the trachea stretched tight—the beam struck him over the top of the sternum and knocked him down. He was not rendered unconscious, but seemed to be short of breath, and could only speak in a whisper. The patient was a strong, well-developed man. On admission he was slightly cyanosed, his breathing being laboured and occasionally stridulous. He was spitting up large quantities of blood, frequently in clots. On examination of the seat of injury a bruise was seen about six inches in diameter, the centre of which was over the upper border of the manubrium, and at this point the skin was scraped off. Round this bruise, covering the front of the neck and extending laterally to the coracoid processes and downwards to a point on a level with the fourth rib was a soft, diffuse swelling, which on palpation gave the characteristic crackling of surgical emphysema. It completely obliterated all the landmarks of the surface affected. No fracture could be made out, the clavicles, the ribs, and the sternum being apparently intact. It was quite impossible to feel the larynx or any part of the trachea owing to the emphysema. Ice was applied to the parts, and with a view to preventing, if possible, the supervention of septic pneumonia antiseptic inhalations were given. The bleeding soon ceased, but, despite all precautions, the temperature gradually rose, and on the third day reached 104° F. Signs of consolidation then appeared at the base of the right lung. The expectoration was blood-stained and amounted to a pint in the twenty-four hours. There was still marked tenderness over the episternal notch, but no sense of fluctuation could be felt, and there was no redness of the skin. In the course of the next few days the signs in the lung almost disappeared, the emphysema decreased, and the temperature fell to a daily maximum of 99°. The patient continued to improve and seemed to be nearly out of danger when, on the morning of May 1st, eleven days after the accident, he suddenly cried out, two or three pints of blood gushed from his mouth, and in less than two minutes he was dead.

Necropsy.—At the post-mortem examination a complete rupture of the trachea was found between the ninth and tenth rings. The ends were separated by about two inches, the upper end of the lower fragment being one and a half inches below the top of the sternum. An abscess cavity surrounded the injured portions capable of containing an ounce; it was filled with blood-clot. None of the large arteries were wounded, and it seems probable that the blood came from ulceration of a large vein, possibly the left innominate.

Remarks by Mr. BARLING.—Rupture of the trachea is certainly a rare accident, and on this account the above example seems to be worthy of record. Besides the cases mentioned in Holmes's "System of Surgery" there is one in the Sydenham Society's *Review* and a case is reported by Berger in the *Medical Times and Gazette* for 1856; this was caused by the kick of a horse and ended fatally in one and a half hours. Of the rest, only one—the Liverpool case—recovered. This was treated by incision. Looking back in the light of our present knowledge it seems as though the patient might have had a better chance of recovery if he had been operated upon. The propriety of cutting down upon the trachea and then proceeding as the conditions demanded was discussed, but the state of the man seemed so satisfactory that it was decided to wait. When the unfortunate rupture which caused his death took place the patient was certainly improving. His temperature had fallen to the normal and the expectorated pus had much decreased in quantity. If an incision had been made it would have given a more free vent to the discharge but anything in the nature of suturing the trachea would have been, I think, impossible, owing to the retraction into the thorax of the divided lower portion. In reporting this case, at Mr. Alcock's wish, I am trying to carry out the advice that our old master, Sir Richard Wiseman, so rightly gives. Speaking to a young surgeon in difficulties with an obstinate case he says: "He will then wish that all other practitioners had done what I have in this treatise—viz., recommended their observations both *successful* and *unsuccessful*, thereby encreasing knowledge in our profession and leaving sea-marks for the discovery of such rocks as they themselves have split upon before."

Reviews and Notices of Books.

System of Diseases of the Eye. By American, British, Dutch, French, German, and Spanish authors. Edited by W. F. NORRIS, A.M., M.D., and CHARLES A. OLIVER, A.M., M.D., of Philadelphia, Pennsylvania, U.S.A. Vol. II. With Thirteen Plates and 214 text Illustrations. London and Philadelphia: J. B. Lippincott Co. 1897. Pp. 556. Price $20.00, subscription for four volumes.

THE second volume of this important work is devoted to the Examination of the Eye, School Hygiene, the Statistics of Blindness, and Antisepsis. These several subjects are again sub-divided and discussed under various headings which we shall proceed to consider. The first is on the Methods of Determining the Acuity of Vision, by Hermann Snellen, of Utrecht, which has been translated by Dr. Berry, of Edinburgh. He explains the reasons which have caused the five minute angle to be selected as a standard, showing that an object subtending that angle fairly represents the average of normal visual acuity, with moderate illumination in middle life. It is, however, by no means the maximum since careful experiment has shown that the limit of visual acuity for lines does not exceed about fifty seconds, which corresponds to a retinal image having a diameter of 0·004 millimetre. Professor Snellen dwells upon the unsatisfactory nature of any statement made in regard to the vision of a patient when, instead of the equation $v = \frac{d}{D}$ where the numerator gives the precise distance at which the test type should be seen whilst the denominator gives the number and consequently the size of the type actually seen, the surgeon reduces the fraction to decimals, a method that fails to give either of the particulars required—giving, that is, neither the distance nor the number of the letters employed. He explains, however, that this notation is practised in Germany because the calculation of the amount of compensation for eye accidents has been based on this principle. Professor Snellen states that as a rule the visual acuity remains unaltered up to the age of twenty-five years. After that it slowly and regularly diminishes, so that in advanced life the measure of acuity is reduced to half of its original. The subject of mydriatics and myotics is also from the pen of Professor Snellen. He gives a useful caution against the employment of solutions of atropine which are too strong or too persistently used, or which have been kept too long. Solutions freshly made of from one to two grains per ounce fulfil all the indications, dilating the pupil fully and paralysing the accommodation. He himself uses atropine in solution of one-half per cent. with the addition of boric acid, and has never observed the condition known as atropism to follow its use. The relative power of the several and now

Digitized by Google

very numerous remedies acting on the iris and on the ciliary muscle is very fully given.

The next article is on Lateral Illumination, by L. Laqueur, M.D., of Strassburg, translated by Harry Friedenwald, M.D., of Baltimore. The author describes the method of employment of this means of examination of the eye, its advantages and limitations both in health and disease. It is, of course, chiefly serviceable in affections of the cornea, iris, and more particularly in the demonstration of fragments of capsule occupying the area of the pupil after cataract operations and the presence of foreign bodies in the anterior chamber or on the surface of the lens.

The subject of the Ophthalmoscope has been committed to the competent hands of Dr. George M. Gould, of Philadelphia, who has compressed all that is required into a very moderate compass. He gives an historical account of the development of the instrument, and considers the most perfect form hitherto devised to be that of Dr. Morton, of London.

Dr. Edward Jackson, of Philadelphia, is the author of the article on Skiascopy. He is well known as having paid great attention to the phenomena of the reflection of light from the fundus of the eye, and he gives, as might be anticipated, a very clear and intelligible explanation of the various appearances seen in myopia, hypermetropia, and in astigmatism.

The sixth chapter is by M. Adolphe Javal, junior, of Paris, on Ophthalmometry and its Clinical Applications. It contains, of course, a full description of the ophthalmometer of Javal and Schiotz, an instrument that has proved of great service in enabling the practitioner to determine rapidly and, what is of still greater importance, accurately the degree of corneal astigmatism that may be present in the eye examined. The number of those who suffer from astigmatism is very considerable. Of a total of 226 children 69 were demonstrated by this instrument to have astigmatism of at least one dioptre in each eye—that is, of a grade so high that it ought to have been reported to the parents with a warning as to the necessity of calling in the aid of an ophthalmic surgeon. The use of a Placido's disk is given, and various drawings exhibit the reflections seen in normal and diseased eyes.

The next chapter is on Prisms and Prismometry, by W. S. Dennett, M.D., of New York, an original and well-written essay on a subject that is very briefly and imperfectly treated in most of the modern works on ophthalmology. A section on the principles of, and the methods for, the estimation of the balance of the extra-ocular muscles has been undertaken by Dr. George T. Stevens, of New York, and in this the reader will find an explanation of the various terms that are making their way from America into ophthalmic terminology, such as orthophoria, heterophoria, heterotropia, and anotropia or katotropia. Dr. Stevens has himself devised an instrument, to which he has applied the name of phorometer, which he describes and illustrates, as well as the prism of Maddox and the stenopœic lens of Stevens. The author of this chapter takes the standard of abduction to be a prism of 8° the effect of which can be overcome—that is to say, the two images of which can be fused.

Dr. Herman Wilbrand takes up Perimetry and contributes a long and valuable article, in which the modes of obtaining the field of vision are described and some remarkable conditions mentioned. The author has devised an ingenious modification of the ordinary instrument, which resembles a reading desk, and which he terms a bed perimeter. It is adapted for taking the field of a patient in bed. The clinical value of perimetry is judiciously but strongly insisted on. The article is illustrated by a chromolithograph showing the most important combinations of the visual paths, as described by Henschen.

The next article, one of the *pièces de résistance* of the volume, is by Dr. Wm. Thomson, of Philadelphia, assisted by Dr. Carl Weiland, of the same city, and is devoted to the detection of colour blindness. The authors consider that with regard to congenital colour blindness, the fault lies in the photo-chemical substances in the retina, or at least that it is located in front of the chiasma, since cases of monocular colour blindness are on record. On the contrary, acquired colour blindness, they believe, is more apt to be due to lesion of the optic nerve or of the cerebral centres. It is stated that even yet in America, as in England, although nearly a million of men are employed on railways, amongst whom there must be at least 30,000 who are colour blind, no adequate provision is made for testing the colour vision, notwithstanding the manifest danger to the public from misapprehension of signals.

Dr. S. D. Risley, of Philadelphia, gives a good account of School Hygiene, a subject far too much neglected in this country. Speaking of the effects of education in the etiology of myopia Dr. Risley states that from careful observation, continued over long periods of time, of many cases of myopia, all those he has followed out, without exception, passed from hypermetropia into near sight; through the turnstile of astigmatism. In all of them the observed changes in refraction were attended with pain and symptoms of external irritation, such as blepharitis, conjunctival congestion, lacrymation, undue sensitiveness to light, whilst the ophthalmoscope revealed the advancing pathological changes in the choroid. In no instance did the eyes become at any period emmetropic. Dr. Risley gives the results of an investigation undertaken by competent observers, to each of whom was assigned a definite part in the examination of every pupil, of the eyes of the children in the various grades of the Philadelphia public schools. The results which are given, in part in the form of tables, are highly interesting and instructive, and demonstrate that all children who complain of their vision should be examined periodically, and measure both in the way of glasses and of amount and kind of work instituted for their relief. The subject of blindness has been placed under the care of Dr. J. Ninnis Hays, of Philadelphia. The statistics of the blind in various countries are fully given, though some error must have crept into the statement that the population of the whole world is below 210 000,000. The population of Russia, England, France, and Germany alone would more than cover that number. The statement is copied (correctly) from Cohn, who takes it from Mayr. It is of importance, since deductions are drawn from it which also work out incorrectly. The number of blind in England and Wales has considerably diminished during the last forty years, which we may hope is due to better teaching given and knowledge obtained in our hospitals. Dr. Joseph A. Andrews, of New York, takes up the subject of Antiseptics, and the volume concludes with an article written conjointly by Dr. Joseph McFarland, of Philadelphia, and Dr. Samuel S. Kneass, of Philadelphia, both articles dealing with germs and their varieties, and with the modes of preventing their injurious influence. There is an excellent index.

Atlas der Gerichtlichen Medizin. (*Atlas of Forensic Medicine.*) Von Hofrat Professor Dr. E. RITTER VON HOFMANN, Director des Gerichtlich-Medizin. Instituts in Wien. München: J. F. Lehmann. 1898. Fifty-six coloured and 193 plain Illustrations. Price 15 marks.

LECTURES at our English Medical Schools on Medical Jurisprudence are as a rule not very satisfactory, owing to the want of practical experience on the part of the lecturers. At some of the London schools there are notable exceptions, but in most instances the lecturer has to draw the materials for his course from books alone. The student has to rely almost entirely on the lectures and books, for it is an uncommon occurrence for a case of real medical legal interest

Digitized by Google

to be taken to the hospital, and even if an injured person be admitted to the wards of a hospital the case is presented to the students from a surgical rather than from a forensic point of view. The illustrations in our English text-books are poor compared to some of the foreign productions. The work now under consideration is one of the excellent "hand atlases" published by J. F. Lehmann, of München. Like its predecessors, reviews of which have from time to time appeared in our columns, the whole book is most excellently produced. The main feature is the illustrations, and of these we cannot speak too highly. That some of them are ghastly goes without saying, but they admirably serve the purpose for which they are intended—namely, to act as a companion to one of the ordinary text-books. Professor von Hofmann states in his preface that the "atlas" is not intended to take the place of a text-book and therefore no systematic discussion of the subject is attempted. Typical examples of the various problems which present themselves to the medical jurist are taken, and an illustration in colour or in black and white accompanies the text.

We trust that an English translation will speedily be prepared, and feel sure that students and practitioners will gain much information by a study of its pages.

LIBRARY TABLE.

The Analysis of Food and Drugs. Part I., Milk and Milk Products. By T. H. PEARMAIN and C. G. MOOR, M.A. London: Baillière, Tindall, and Cox. 1897. Price 5*s.*—This work promises to be an admirable work of reference on all that pertains to the analysis of food and drugs. The number before us is only the first part of the work, which, when complete, will be divided into five parts. Apparently, the object of issuing the parts separately in this way as they are written is to keep each portion as far as possible up-to-date. Whether or not this object will be gained will depend, of course, upon the time the authors mean to take to complete their task, as it may be that when the final sections are finished the earlier sections may require adding to, especially if the improvements in analytical methods go on at the present rate. The work is very clearly written and bears strong evidence of the authors practical acquaintance with the "up-to-date" methods they describe. We look forward to the issue of the succeeding sections, which Part I. leads us to hope will be equally ably treated. Mr. Pearmain and Mr. Moor have begun their task well, and when they have finished it a valuable addition to analytical literature will, if we mistake not, have been made.

Artificial Anæsthesia: A Manual of Anæsthetic Agents and their Employment in the Treatment of Disease. By LAURENCE TURNBULL, M.D., Ph.G. Fourth edition. Philadelphia: P. Blakiston. 1896. Illustrated. Pp. 550.—This book contains a large amount or information about anæsthetics and many other things. It is not always easy to find the kind of information required, as the arrangement is not good. Dr. Turnbull prefers to quote the writings of many writers, with a result which is wearying to the reader, who often would prefer to get the underlying fact without the superimposed mass of words. The author is well abreast of the time, and gives the views of the Hyderabad Commission on Chloroform. Although he questions their truth, he describes the use of oxygen with nitrous oxide, and the very latest local anæsthetic. Therapeutics occupy a prominent place in the book. The employment of ether in gout, spasm of the stomach, tapeworm, and other ailments is fully set forth. A good chapter on the medico-legal aspect of the uses of anæsthetics is added. We venture to think that Dr. Turnbull would be well advised if he cut out many of the so-called experiments in future editions and condensed and verified most of the quotations. The undoubted value of Dr. Turnbull's work is also somewhat marred by insufficient care in verifying names. The present is, in spite of these drawbacks, a distinctly better book than the preceding edition.

The Induction Coil in Practical Work, including X Rays. By LEWIS WRIGHT. London: Macmillan and Co. 1897.—All workers with the x rays should be in possession of a copy of this little volume. In it is contained a plain and intelligent exposition of that mysterious entity electricity, and the properties of the electric discharge in low and high vacua, leading, of course, to a consideration of the phenomena of the x rays which emanate from the highly exhausted Crookes's tube. It is essentially a practical book, in which the eccentricities of the induction coil are dealt with and the way to correct them, so that the experimenter may know perfectly well what he is doing in using the x rays for diagnostic work.

Practical Domestic Hygiene. By J. LANE NOTTER, M.A., M.D. Dub., and R. H. FIRTH, F.R.C.S. Eng. London: Longmans, Green, and Co. 1897. Price 2*s.* 6*d.*—Hygiene is a wide subject, and the fact that they have dealt with it intelligibly in the space of the admirable little work before us is an accomplishment upon which the authors are to be congratulated. The subject is treated in three parts—Part I. relating to Elementary Human Anatomy and Physiology; Part II. to Elementary Hygiene (water, air, ventilation, food, diet, sewage, personal hygiene, parasitic and infective diseases); and Part III. to Domestic Economy (the care and management of the sick, and "first aid" in emergencies and accidents). As might be expected, Part II. is the largest section. The descriptions are perfectly accurate, clear, and in accordance with modern developments. Particularly will this be noticed in regard to the accounts of the methods now in vogue of ventilation and of the disposal of sewage and of house refuse and excreta. The work is primarily intended for those who wish to acquire a knowledge of elementary hygiene but who possess the merest smattering or no knowledge at all of physiology. The previous portions of the work are therefore devoted to a short and simple account of elementary anatomy and physiology, but there is no similar chapter on chemistry. We are inclined to think that this in an elementary work is a serious omission, since, of course, the reader is subsequently brought to consider the subject of diet, and without an elementary knowledge of chemistry his appreciation of the subject as well as of other related subjects will somewhat suffer. The whole subject, however, in its broader aspects is presented in a way which cannot fail to be instructive to the reader possessing ordinary intelligence. We could wish that such a course of instruction were insisted upon in all elementary schools; the present book would serve as an admirable companion to such a course.

A New Dairy Industry. By JAMES FRED. SARG. Norfolk, U.S.A.: W. T. Barron and Co. 1896. Pp. 162.—It is well known that the principal difference from a dietetic point of view between human milk and cow's milk is that the latter contains about four times as much casein as the former, and that most methods of preparing cow's milk for infants' use consist in reducing the proportion of casein and increasing that of sugar. Furthermore, cow's milk is liable to be contaminated with impurities of various kinds, and sometimes contains pathogenic bacteria. This little book, the sub-title of which is "Preparation and Sale of Artificial Mothers' Milk, Normal Infants' Milk," describes the methods followed in Mr. Sarg's dairy at Black Forest Farm, Kempsville, Virginia, and supplies much varied information, useful alike to consumers and purveyors of milk. In this establishment the excess of casein is reduced by dividing the milk into two parts, one of them consisting of mixed milk and cream and

Digitized by Google

the other of skim milk, which latter is coagulated and the resulting whey added to the other portion; the mixture is then bottled and sterilised by steam heat.

The Story of Vaccination. By ANNABELLA MARIA BROWNE. London: Gardner, Darton, and Co. 1896. Pp. 12. Price 1*s.*—The author of this booklet has described the benefits of vaccination with much clearness and force, as well as with commendable brevity, and in a style which can be easily followed by all classes of readers. She is president of the Gloucester and Bristol Branch of the Girls' Friendly Society, which she says has had among its members several descendents of the family of Sarah Nelmes, the dairymaid from whose hand Jenner took the lymph for his first vaccination in 1796. Writing in the centenary year after this event, and not long subsequently to the Gloucester epidemic of small-pox, she is able to contrast the ravages of the disease in former times with the comparative immunity which we now enjoy. "The Story of Vaccination" deserves to be widely known, and will recommend itself to those who are desirous of influencing public opinion in favour of vaccination.

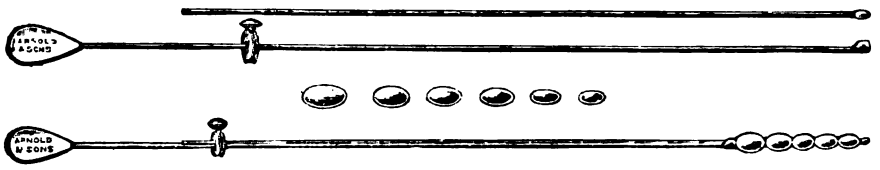
Calendar of the Faculty of Medicine, McGill University, Montreal. Montreal. 1897. Pp. 148.—The educational work of McGill University is carried on principally in McGill College, Montreal; there are, however, six affiliated colleges—namely, four theological colleges in Montreal, Morrin College, Quebec, and St. Francis College, Richmond. At McGill College there are five faculties, in each of which various degrees are granted—namely, arts, applied science, medicine, law, and comparative medicine, together with veterinary science. The complete course of study in medicine extends over four sessions of about nine months each, and leads to the degrees of M.D., C.M. The total fees for the whole medical course, including clinics, laboratory work, dissecting material and reagents, are $400, payable in four annual instalments of $100 each. Last session there were 388 students in the medical faculty, and 76 passed the examinations for the degrees of M.D., C.M. The sixty-fifth session of the medical faculty was opened on Sept. 21st, and will be continued until May 27th, 1898.

Instruments Used in Surgery and Medicine. Compiled by N. H. MARTIN and C. E. STUART, B.Sc. Newcastle-on-Tyne: Brady and Martin. 1897. Pp. 548.—In this book, which is the latest catalogue issued by Messrs. Brady and Martin, there will be found illustrations of a large and varied collection of instruments and appliances adapted for use in every department of medicine and surgery, whether for operative procedures or for diagnosis. There are also illustrations of galvanic apparatus, Roentgen ray apparatus, meteorological instruments, apparatus for the analysis of air, milk, and water, and a variety of miscellaneous articles which may be summarised as sick-room appliances. The book has a handsome appearance and will be found useful as a work of reference.

JOURNALS AND REVIEWS.

The Journal of Physiology. Edited by MICHAEL FOSTER, F.R.S., and J. N. LANGLEY, F.R.S. Vol. XXI., No. 6, and Vol. XXII., Nos. 1 and 2. July and September, 1897. London: C. J. Clay and Sons. No. 6, Vol. XXI., price 4*s.* Nos. 1 and 2, Vol. XXII., price 10*s.*—The last number of the twenty-first volume of this journal contains two articles. 1. John Fawcett and W. Hale White on the Influence of Artificial Respiration and of β-Tetrahydronaphthylamine on the body temperature. These experiments show that this drug has a remarkable pyretic action, 3 c.c. of a 3 per cent. solution when subcutaneously injected raising the temperature of rabbits from 1·6° C. to as much as 5·5° C. 2. H. M. Vernon on the Relation of the Respiratory Exchange of Cold-blooded Animals to Temperature, Part 2, with 14 figures in the text. Amongst other conclusions the author draws from his experiment is the following, that in cold-blooded animals the carbonic acid discharge does not increase and decrease uniformly with increase and decrease of temperature. The following articles are contained in Nos. 1 and 2 of Vol. XXII. 1. C. R. Marshall on the Antagonistic Action of Digitalis and the Members of the Nitrite Group, with nine figures in the text. 2. C. R. Marshall and H. Ll. Heath on the Pharmacology of the Chlorhydrins: a contribution to the study of the relation between chemical constitution and physiological action, with eight figures in the text. The authors show that the introduction of chlorine atoms into a compound of the fatty series increases its narcotic powers. 3. Purves Stewart, on Experimental Observations on the Crossed Adductor Jerk. It is shown that the adductor jerk of the opposite side to that on which the ordinary knee-jerk is evoked is a true reflex. The appearance of the the crossed adductor jerk is about 0·126 second after the tapping of the opposite patellar tendon. 4. J. C. Dunlop, D. Noel Paton, R. Stockman, and Ivison Maccadam, Massage, on the Metabolism. Amongst other results on the Influence of Muscular Exercise, Sweating, and the like, their experiments show that with excessive muscular efforts there is increased katabolism of proteid shown by increased excretions of nitrogen and of sulphur in the urine. The proteid consumed is muscle proteid. They show also that training is of much importance. 5. A. B. Macallum, of Toronto, on a New Method of Distinguishing between Organic and Inorganic Compounds of Iron. 6. C. B. Davenport, of Harvard University, and Helen Perkins, student in Radcliffe College, a Contribution to the Study of Geolaxis in the Higher Animals. 7. Swale Vincent, on the General Physiological Effects of Extracts of the Suprarenal Capsules. 8. D. Noel Paton, on a Further Study of Hepatic Glycogenesis. 9. W. H. R. Rivers, on the Photometry of Coloured Paper. 10. William J. Smith Jerome, on the Formation of Uric Acid in Man and the Influence of Diet on its Daily Output.

The Practitioner.—The first of the original papers in the September number is the continuation of Dr. Herman Weber's paper upon Health Resorts and Waters for the Anæmic. Anæmia being a condition which arises from a great variety of causes must be treated in a correspondingly varying manner, and Dr. Weber's paper will be found very valuable as a guide to the choice of the right water for the special class of anæmia under consideration. Mr. Mayo Robson, in a short but interesting communication pleads earnestly for an early performance of gastrostomy instead of waiting until the patient is reduced by pain or starvation to a state in which the operation is practically useless. He gives details of the plan he prefers—a modification of the Ssabanejews-Franks method. Surgeon-Captain B. H. F. Lewmann publishes a case of Plague Simulating Enteric Fever, the temperature at death reaching 106·2° F. Dr. F. E. Hare, in his paper on Ten Years' Experience of the Cold Bath Treatment of Typhoid Fever at the Brisbane Hospital, quotes figures showing a reduction in the mortality of practically 50 per cent. since the use of the bath began. Dr. F. C. Coley has a practical paper on the Medical Treatment of Toothache. Mr. Hawkins-Ambler contributes a paper upon How to Help the Hospitals, his chief idea being that there should be a series of central bureaux at which applicants for hospital relief should apply in the first instance. The hero of medicine for the month is that extraordinary mixture of science and charlatanry—Paracelsus.



THE WATER-SUPPLY OF TAUNTON.—At the meeting of the Taunton Town Council held on Sept. 14th the Water Committee stated that they had instructed the town clerk to give the necessary notice prior to application being made for the sanction of the Local Government Board to the borrowing of £35,100 for the extension of the waterworks.

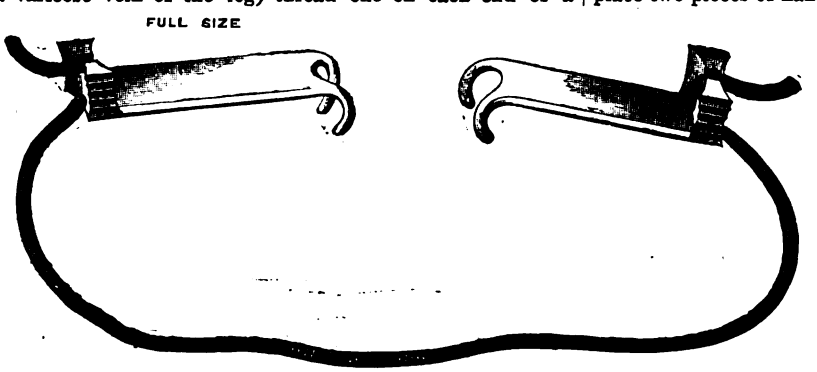
New Inventions.

NEW STRICTURE DILATOR.

MESSRS. ARNOLD AND SONS (of West Smithfield, London) have constructed for me an instrument which I hope will be appreciated by the profession. The troublesome and painful system of passing catheters and bougies for strictures ought certainly to be superseded by some procedure less irritating to the patient and more convenient to the practitioner.



The instrument illustrated here consists of a director, a propeller, and twelve beads. The director is a flexible metal stem terminating in a bulb, the stem being marked at every half inch. The propeller, which is used to push the beads along the director, has a terminal bulb (perforated), a handle, and a metal ring with hole to receive director and screw to clamp it. The beads are made of metal and represent the different catheter gauges. The director is passed first, then one or more beads are threaded on it and pushed home. The instrument may then be fixed and withdrawn. Possibly in resilient and other strictures the act of drawing the instrument back and forwards would have a good effect. The exact position of the stricture can be ascertained by passing a bead as far as the stricture and then clamping the ring at the orifice of the urethra.

THOMAS JACKSON, L.R.C.S.Edin.
Colwyn Bay.

AUTOMATIC WOUND RETRACTORS.

THE accompanying illustration represents a pair of wound retractors threaded on a rubber cord, and designed to obtain traction on the edges of a wound in operations on the neck, limbs, &c. Each retractor consists of a flat piece of steel, one end of which is fashioned into a pair of hooks, blunt or sharp. The other end is bent upwards, is perforated at the angle by a hole through which the rubber cord passes, and the latter is then clipped into a vertical slot after the manner of fixing the ends of a field tourniquet. The instrument may be held or altered in position by grasping the grooved side of the "handle" portion. To use the retractors (say, for excision of a varicose vein of the leg) thread one on each end of a long length of rubber cord or thick tubing and lay its centre beneath the limb; after the skin incision hook a retractor into the wound edges on either side, making the tension sufficient by drawing the cord through the base of either hook and fastening off. Equal or unequal gaping of the wound may be secured by altering the tension on both sides or on one only. The retractors are made of varying sizes and lengths, and with blunt or sharp hooks as desired, but for retracting the abdominal parietes the proximal end is fashioned like a flat pothook but without prongs. For tracheotomy and operations on the middle line of the neck, operations on blood-vessels of the limbs, abdominal sections, and in any situation where bilateral traction can be employed, these retractors will be found useful, especially where one is short-handed as regards assistants.

FULL SIZE

Some of the advantages possessed by these hooks are:—Less handling of the wound is required; more room is obtained in which to work, and less assistance is necessary; it is, therefore, more easy to maintain asepsis. I am indebted to Professor Jordan Lloyd, of Birmingham, for permission to modify his well-known retractors, and to Messrs. Down Bros., of St. Thomas's-street, London, S.E., for the care and patience they have displayed in carrying out my wishes.

REGINALD H. LUCY, M.B. Edin., F.R.C.S. Eng.,
Assistant Surgeon, South Devon Hospital, Plymouth.

NEW ANÆSTHETIC MASK.

THE annexed illustrations represent a chloroform or A.C.E. mask devised by me and made by Messrs. Mayer and Meltzer, of Great Portland-street. The mask consists of a metal frame, with upper and lower rims, the latter being channeled so as to prevent condensation-moisture or anæsthetic fluid reaching the patient's face. A and B (Fig. 1) represent the open position of two rings which, when closed as in the illustration, keep in place two pieces of flannel. At C there is an airway the lumen of which is quite double that of the adult trachea. At D (Fig. 2) there is an opening for the tube of a Junker which can be attached to a vulcanite plug filling the opening. This tube is supplied with the mask. Also, to the flannel at E a sponge can be affixed if it be desired to give ether, in which case a single piece of flannel large enough to cover the mask from E to F should be used. The advantages of the mask are:—1. It allows a free intake of air at all times during anæsthetisation, so that with ordinary care coughing and swallowing, struggling, asphyxia, &c., are noticeably absent. 2. The position and dimension of the airway, which, while permitting absolutely unimpeded respiration, is so placed that with each inspiration the vapour is inhaled in amounts varying with the quantities of anæsthetic used. 3. The ease with which the anæsthetic can be dropped on the mask without risk of touching the patient's face. 4. Its cleanliness. The covers for the upper

Fig. 2.

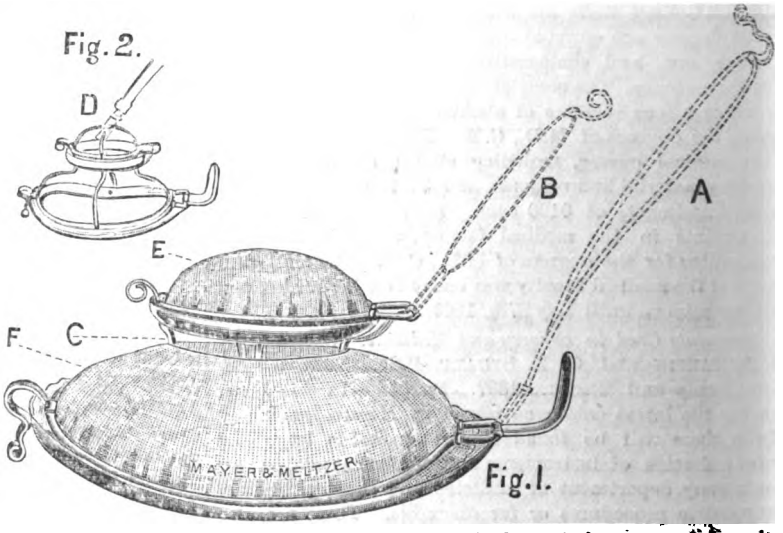


Fig. 1.

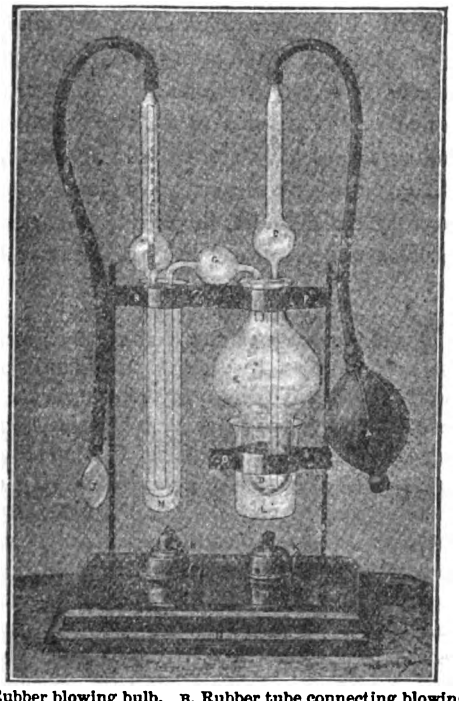
Digitized by Google



and lower parts consist of flannel (sterilised when necessary) cut to shape; these can be put on or removed in a few seconds; the frame, being all of metal, can obviously be completely sterilised—matters of considerable importance in the case of operations on the head, neck, thorax, &c. 5. A chloroform administration can, if desirable, be commenced by using with this mask a drop bottle, such as Thomas's, &c., until the patient is well into the second stage, when the remainder of the anæsthetisation can be continued with a Junker (attached to the mask in the first instance). The anæsthetist who knows the difficulty of getting a nervous or alcoholic patient comfortably under within a short period possesses in this apparatus the means of accomplishing that end with safety and satisfaction. The patient also hears nothing of the bellows and the bubbling of the Junker. This latter consideration is by no means unimportant when one bears in mind how desirable it is to avoid adding to the natural fears of a child or neurotic patient.

WILLIAM E. BURTON, L.R.C.S.Irel., Lic. Med. T.C.D.

THE PNEUMATIC MEDICATOR AND INJECTOR.

MEDICATED AIR has been in use in America for some years for the treatment of catarrh of the head, ears, nose, throat, and lungs with marked success, and especially for the cure of catarrhal deafness. It has lately been introduced into Great Britain and has been equally successful. But it appeared to me that better results would be obtained in many cases—such as bronchitis and phthisis—if the temperature of the medicated air could be raised or lowered, made dry or moist, as the conditions of the case required,

Instrument for Producing Hot or Cold, Dry or Moist, Medicated Air.

A, Rubber blowing bulb. B, Rubber tube connecting blowing bulb with straight glass tube. C, Straight glass tube. D, Reservoir for holding medicine. E, Air chamber for medicated air. F, Rubber cork for holding glass tubes. G, Long bent glass tube containing thermometer. H, Thermometer in long bent glass tube. I, Rubber tube connecting long bent glass tube with mouth- or nose-piece. J, Glass nose- or mouth-piece. K, Spirit lamp for heating water baths. L, Water bath for heating medicine in reservoir or for cooling medicine by filling with ice. M, Water bath for heating medicated air in long bent glass tube which passes through it. N, Stand containing spirit lamp. O, Holder for supporting water bath. P, Holder for supporting air chamber and reservoir. R, Holder for supporting long water bath.

as up to the present the medicated air has only been used in a dry state at the temperature of the room in which the patient used the instrument. To meet these requirements where better results would be obtained by raising or lowering the temperature and making the heated medicated air dry or moist, I have constructed an instrument with which the patient can either use the medicated air at the temperature of the room in which the instrument is used or the temperature can be raised or lowered, and the heated medicated air can also be made dry or moist as may be required by the nature of the case.

D. JOHNSTON, L.R.C.P. Edin., &c.

NINETEENTH REPORT OF THE GENERAL PRISONS BOARD, IRELAND.

IN his work on "Penological and Preventive Principles" the secretary of the Howard Association has referred in complimentary terms to the successful methods employed in the management of the Irish prisons. That the same policy is still being pursued is apparent from a perusal of the present report, which contains evidence that the Irish Prison Commissioners are concerned in maintaining a high standard of efficiency in the administration of the establishments under their charge. It is more than probable that the satisfactory state of affairs revealed in the report is in a measure due to the fact that one of the members of the Irish Board is a representative of the medical profession. In this respect both the English and Scottish Boards labour under a distinct disadvantage, for there can be no doubt that the question of the treatment of the criminal is gradually but surely assuming a more scientific aspect. His physical and psychological peculiarities are being extensively and exhaustively studied, and the relations of insanity and crime are constantly attracting attention. The health of prisoners, mental as well as bodily, their dietary, and their sanitary surroundings are matters of weighty importance, deserving special recognition and requiring skilled supervision. The report now under consideration is the record of a year's quiet and uneventful work. The course recently adopted in England of amalgamating the statistics of the local and convict prisons has been followed here. There has been a slight increase in the number of criminal prisoners committed to local prisons. The behaviour has been good, and it is gratifying to note a gradual diminution in the number of prison punishments during the past few years. The death-rate was remarkably low—viz., 2 56 per 1000. One suicide is reported. Three cases of typhoid fever occurred, but it is mentioned that the disease was incubating when the prisoners were admitted. Sixty-two prisoners were released on medical grounds; they included the cases of twenty-three women far advanced in pregnancy. There were 103 cases of insanity, being 28 in excess of the number in the previous year. Eighty were found to be insane on reception, and the remainder whilst undergoing sentence. Particulars of the individual cases are given in Table XIV. As it stands, this table is not of much practical value. With further detailed analysis and subdivision it would undoubtedly prove useful, both from a psychical and medico-legal point of view. The average daily population of the local prisons was 2335; that of the convict prisons was only 429. The conduct of the long-sentence prisoners seems to have been exemplary, and in no instance was corporal punishment resorted to. One convict died, ten were released on medical grounds, and six became insane and were transferred to the Central Criminal Asylum at Dundrum. The number of juveniles convicted and sent to prison is annually becoming less. Special rules have been adopted for their treatment; the operation of these rules ought to prove beneficial. The whole report affords evidence that the duties of the Board are being discharged in a creditable manner.

CLINICAL DEMONSTRATIONS TO PRACTITIONERS.—At the request of the Glasgow Town Council the visiting physician to the city fever hospital at Belvidere has agreed to give a series of clinical demonstrations on the cases of small-pox under treatment in the hospital. The demonstrations are free to all practitioners who conform to the conditions as to re-vaccination and such other precautions as are very properly demanded. There can be no doubt that this arrangement will be welcomed by the profession, and all the more so that—fortunately from a public point of view—opportunities for seeing small-pox are now so rare in the city.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 25, 1897.

THERE is one sentiment in regard to the vacancy in the Direct Representation (for notwithstanding Dr. RENTOUL'S withdrawal of his resignation the vacancy remains) which seems to prevail in all quarters—namely, that the position of Direct Representation is a critical one, and that unless the profession can contrive to show more interest in it and to return with some approach to unanimity a man of power and one who can coöperate amicably with the General Medical Council, even as at present constituted, the prospects of any early extension of the principle in legislation may be abandoned. Wherever two men meet and discuss this subject it is with a feeling that Direct Representation is not working satisfactorily or in a way to induce practical statesmen to multiply the number of elected members of the General Medical Council. We do not look upon this as a permanent feeling. It will pass away with a larger experience in the profession of its own members and a greater familiarity with the questions of medical education and medical conduct with which the General Medical Council has to deal. It is unreasonable to expect that registered general practitioners, busily occupied in their own particular duties, should all at once realise the functions of the General Medical Council, or estimate the kind of representative whom they should send to the Council. The painful want of readiness in the profession to meet and deal with an emergency such as has arisen from the unexpected resignation of one of its Direct Representatives is emphasised by one circumstance. The vacancy occurs when everybody is supposed to be taking holiday. But this only brings into clearer light what was manifest enough before—that there is a want of organisation in the profession. Efficient organisations and associations do not take holidays. They should be always in evidence.

For the purpose of the imminent election to the General Medical Council we are 22,000 separate units, and the enthusiasm of the profession for Direct Representation has never yet been demonstrated, as far as we know, by a meeting of a hundred persons. We see no immediate sign of any efficient organisation for this purpose. And yet the occasion is an urgent one. The Medical Acts are in need of amendment; the public is duped with quackery; the profession is overcrowded beyond all public necessity or advantage; its members, after the most exacting and exhausting processes of education and examination, are unprivileged and unprotected from the grossest forms of competition; and loose systems of registration permit the public to remain ignorant of the fact that numbers die without receiving any proper medical attention. A wise and efficient Direct Representative can certainly advance the remedy of these evils. It only remains for the members of the profession individually to recognise their own responsibility. We repeat that in our opinion the doubt and apathy about Direct Representation are transient and will pass with time and a larger experience of the duties which such a system imposes. The very men who have most abstained from using their votes should now determine to use them and urge all their friends to do likewise. They are numerous enough to decide the election and to return such a member as will be a credit to the principle of Direct Representation. The list of candidates is not, perhaps, yet complete, but it must soon be so, and it will not be without the names of one or two candidates who would justify the concentration of the votes of the profession. What we plead for now is this concentration—that there be no repetition of the indications of indecision and division and abstention which were so apparent at the last election. The present vacancy is a huge inconvenience and expense to the Council. But it will not be an unmixed evil if it results in the restoration of the comparative unity of the profession and in the return of a Direct Representative who is in sympathy with the practitioners of the country and who is prepared to use the present Medical Acts, in so far as they are efficient, for the good of the public and the profession, while he is determined, wherever they are defective, to promote their amendment in a spirit of moderation and medical statesmanship.

THE annual Congress of the Sanitary Institute, which has just been held at Leeds, has done some good and useful work. During the course of the debates the remark was made that in regard to sanitary reform it was more necessary to educate than to legislate. It is an old and true axiom that peoples have the governments they deserve. Even under the most absolute despotism it is the people who make the government and not the government the people. So in respect to the laws for the protection of public health, such laws only are effective which the public thoroughly appreciate and approve. Therefore the first step is to educate the people, and in this respect we are not only pleased to note the holding of such congresses as those organised by the Sanitary Institute, but also that the proceedings at these meetings are very fully and ably reported by the local press. Further, great good is done during the Congress week by the holding of public meetings where men of science attending the Congress deliver, in simple and popular language, addresses on public health questions. While, however, we thus fully acknowledge the paramount importance of educating the people in matters appertaining to the preservation of health, it would be a great mistake to conclude that the ignorance or

Digitized by Google

indifference of the masses is the only obstacle in the way of sanitary reform. During the course of the debates a good deal was said concerning the disposal of sewage and the pollution of water-courses. This is a question which more particularly affects the great manufacturing towns and districts of Lancashire and Yorkshire. No one can deny that, for instance, the Manchester canal is a national scandal. This magnificent engineering achievement is polluted by the drainage of seventy sanitary districts; and what should be a noble water-course is nothing better than an open and foul sewer. Yet it would be manifestly unfair to blame the people for the disgraceful condition of the Manchester canal. The cause of the evil may be roughly described as twofold—namely, the supineness of the local authorities and the greed or selfishness of the local land-owners. The members of the local boards can scarcely plead ignorance as their excuse. The real fact is that these authorities are composed, in the main, of manufacturers who are themselves the principal polluters of the four watersheds that feed the Manchester canal. The people have no objection to the purification of the waste waters from factories and mills; it is the mill-owners who wish to avoid the necessary expense. On the other hand, when, reluctantly yielding to pressure from the Local Government Board and to the outcry of public opinion, these local authorities have made some attempt to deal with their sewage, the land-owners have either refused to sell the land required for such treatment or have demanded a prohibitive price. A good excuse for doing nothing at all was thus supplied to those authorities, who were too often only too pleased to avail themselves of any pretext for shelving the whole question. In a series of special articles which we published in October and November, 1893, this condition of affairs was set forth in full detail. Consequently we are compelled to conclude that if the people want educating as to the facts and principles of sanitation, the local authorities, the governing and privileged classes generally, are in equal need of education as to their duties in helping to apply the theories taught to the humbler members of the community.

Nor was it necessary for the Congress to go beyond the confines of the town of Leeds to find an example of this necessity. Leeds is essentially a town of back-to-back houses, and even at this late hour the town authorities do not seem to be fully convinced as to the evils of this system. Though Ireland can scarcely be considered as a country which has taken the lead in the practical application of sanitary principles, it devolved on Dr. MUNTZ, of Belfast, when speaking on this subject at the Congress, to congratulate the Local Government Board on having refused to permit the Corporation of Leeds to erect back-to-back houses in the place of those to be demolished. We are glad to note that these words were greeted with loud applause by the Congress. Nevertheless, Councillor WOMERSLEY attempted to make a sort of apology for back-to-back houses, and this, too, before an audience composed exclusively of sanitary reformers. To make matters worse, Councillor WOMERSLEY said that there was no comparison between the older specimens of back-to-back houses and those recently erected. Surely the fact that such houses have been recently erected is the worst of all sins against the principles of sanitary science. We can forgive what was done before the unhealthiness of back-to-back houses was realised, demonstrated, and understood. Now, however, that the unsuitable nature of such dwellings is all but universally acknowledged what possible excuse can there be for having recently erected such buildings? Yet there are numerous streets—and good streets, not mere slums—in Leeds where modern houses stand back to back and can have no through ventilation. Evidently education in sanitation must be extended to other classes than those which are usually considered to compose what is called "the people." If, however, the Corporation of Leeds has exposed itself to severe criticism with regard to its lax opinions on the subject of back-to-back houses, it deserves encouragement in its efforts to grapple with the very difficult problem of the housing of the poor. As Councillor WOMERSLEY rightly observed, it is no easy matter to deal with seventy-two acres in the centre of a great city like Leeds, and to house and re-house 15,000 people.

A good deal was said at the Congress as to the teaching of hygiene in elementary schools and as to the educational influence in such respects which might be exercised by the clergy as well as by women in general. There is no doubt that much more could be done in this direction than is at present attempted. Still we have seen notable beginnings in various directions, and it may confidently be asserted that knowledge of the elementary principles of hygiene is more widespread among British people than among the peoples of most Continental countries. In one important respect the poorer classes in England are much behind similar classes on the Continent. The poorer classes in England know more about public and less about personal hygiene than similar classes in most of the Continental countries. The poor of England have a better knowledge of the measures that should be taken to prevent the spread of infectious diseases and of the importance of good drainage and ventilation; but they are inferior to similar populations on the Continent in respect to the care of their persons, their clothes, and their food. The popular lecture delivered at the Albert Hall, Leeds, by Dr. P. BOOBBYER, medical officer of health of Nottingham, was therefore most appropriate. He spoke of the sterilisation of milk, the amount of meals that should be taken, and how a steak should be cooked. It is homely advice of this sort that is much needed in this country. Anyone who is familiar, not only with the slums of the great English centres, but also with those of Continental cities, will have realised that whereas on the Continent the sanitation or drainage is infinitely worse than in England, the furniture, especially the bedding, is cleaner, the people are more tidily dressed, and in spite of their poverty their cooking is immeasurably superior. In such respects the standard of life is higher and the refinement is greater. These are questions which sanitary reformers might with advantage take in hand. It is on our weak points that we need the most enlightenment.

THAT many of our medical terms are a standing testimony to etymological ingenuity and philological inventiveness will be readily admitted, and the uncouth cumbrousness which expresses so little at so great length makes all but the very learned ready to listen to any reasonable plan of reducing to simplicity the polysyllabic acrostics without which science

Digitized by Google

and art seem unable to advance. Unsupplied with an up-to-date medical dictionary it is impossible for any who have not kept in close touch with all the developments of our art to read intelligently the literary productions which describe them. Words to try the articulation as well as confound the understanding have been devised, and it is not easy to see who derives benefit therefrom. The medical student, indeed, dearly loves a long, high-sounding word; it is a precious thing to be stored in the recesses of his mind ready for the first examiner who gives him an opportunity to exhibit it. As ROBERT LOUIS STEVENSON'S funniest creation, Mr. PINKERTON, seized on the "boss word hebdomadary," and said to it, "I'll have you in type as long as yourself," so the student grabs at such words as "choledocho-duodenostomy," and says, "Wait till I find an examiner to hurl you at." The simplification of nomenclature would lessen the temptation the student has to attach himself to a treble-barrelled verbal curiosity rather than to gain an insight into the thing itself, and this alone would make for good. But seriously, the time spent in learning the meaning of medical terms is labour which ought to be reduced to a minimum. Each science has its own phraseology—a phraseology which its votaries must acquire and understand; but this ought at least to be made as easy and simple as possible. Consequently, although the dreams of the spelling reformer are usually Utopian, we cannot but sympathise with the efforts of those who draw periodical attention to the muddles in the spelling of the medical vocabulary.

One of the latest to direct attention to the subject is Dr. GOULD, of Philadelphia, the author of an excellent medical dictionary, and therefore an authority on the subject. We printed Dr. GOULD'S suggestions last week (p. 773) and may now briefly consider his proposals in detail. He makes eight suggestions, it will be seen, in support of what he terms "microscopic modifications." His advice to Anglicise foreign terms which a good proportion of readers will not understand is sound, and we agree to the use of figures rather than spelling when the number to be indicated is more than ten, for space is thus saved, though a source of error is introduced requiring watchfulness. He wishes to abolish the diæresis and all accents. "When a foreign word is Anglicised let us do it completely," he pleads, "and not drag into our domain exotics of foreign habit, leaving it, e.g., neither English nor French." This suggestion we do not consider a good one. It is well that words should have the hall-mark of their origin for some time. When the hall-mark has become unnecessary it will not be imprinted. He also desires to abolish diphthongs with one sweep. Custom has largely brought about the realisation of the suggestion. Examples of abolition of the diphthongs "æ" and "œ" in words where they can be supplanted by "e" are numerous. "Ether" has taken the place of "æther," "perineum" is, though with some difficulty, displacing "perinæum," "empyema" is now never written "empyæma," and though "pyæmia" and "septicæmia" are still in the field, there are signs that in them, as well as in a number of other words, the diphthong may disappear before the single vowel with us, as it has already done in America. The disappearance of the hyphen in compound words must also be left to the working of that powerful force by which changes are silently, almost imperceptibly, effected. In such words as anti-toxin, post-mortem, ventro-fixation, and that series of complicated terms used to designate operations upon the abdominal viscera, the hyphen will probably disappear as we begin to realise that the long words express only a single process or procedure. Antitoxin is already spelt universally without its hyphen. It is in the infancy of new procedures, before the mind has become familiar with their several stages and has instinctively blended them into one compact whole, that hyphens between the parts are so necessary. The separation of the several parts of the word helps the mind to a more ready comprehension of the thing indicated. The hyphen will disappear as our conception of the thing meant becomes easy and complete. Until then the hyphen is far from "useless," as Dr. GOULD terms it, and will remain.

In our opinion Dr. GOULD'S suggestions can all be left with safety to the ordinary evolution of language. By a stroke of the pen it is impossible, as it is, in our opinion, quite inadvisable, to order the dropping of the final "te" in words like curette, fourchette, and brunette, although in tourniquet, minuet, and other words it is missing. Nor will the fiat of any group of reformers suffice to suppress the silent "me" of gramme, centigramme, and the words in which it persists, in spite of its absence from telegram, diagram, anagram, and others. And not even the authority of the American Association for the Advancement of Science will effect the disappearance of the final "e" from bromide, iodide, bromine, iodine, atropine, and other words in which they recommend the change, unless the unconscious impulse of the English-speaking race tends in that direction; and if it does the association is as powerless to prevent as to promote the change. Neither language nor spelling is rigid and unalterable. But suggestions such as those of Dr. GOULD serve a purpose by drawing attention to the need for clearness of nomenclature and simplicity of diction in those who feel themselves compelled to coin new words for us, and for that reason he has done well to throw them on the waters of public opinion. But if any of the suggestions ever come back to him as tangible philological results, it will be not till the lapse of many, perhaps very many, days.

Annotations.

"Ne quid nimis."

THE POWERS OF A CORONER.

AN inquest held some little time ago shows very well the ignorance that exists even among people who might be supposed to know as to the powers and status of a coroner. Shortly, the facts were as follows. An old man found in a dying condition in the road, was seen by one medical practitioner, who forthwith ordered his removal to the infirmary, where he died. Notice of the death being forwarded to the coroner that gentleman ordered the medical man first called in to attend at the infirmary and make a post-mortem examination. The master of the workhouse refused to allow the practitioner in question to obey the coroner's order, although told by the practitioner that he had authority from the coroner. The medical officer of the workhouse also seems to have

Digitized by Google

been under the impression that he should make the examination. At the adjourned inquest the coroner spoke very plainly to both the master and the medical officer, pointing out that they had rendered themselves liable to various penalties for obstructing him through his agent in the performance of their duty. It cannot be too strongly impressed upon every one that a coroner is a judge, and that any obstruction to, or defiance of, his orders is contempt of court. We observe that in the discussion on the matter before the board of guardians one member, Mr. Luck, who distinguished himself the other day in a vaccination controversy, "was of opinion that the inquest was uncalled-for. It was all a question of £ *s. d.*" So, at least, says the report in the *Eastbourne Gazette*.

MIDWIVES.

WHATEVER views may be entertained on the question of a Midwives Bill one thing is becoming clearer every day—that midwives, without any necessary acquaintance with the dangers of childbirth or the most elementary principles on which they should be met, cannot be allowed to continue their work unchecked. Women of the poorer classes must somehow be protected from such an obvious risk to life. A very painful case has been the subject of an inquest at Oldbury—that of a woman, aged forty-two years, who was attended by two persons apparently calling themselves midwives. The deceased had a great objection to the attendance of a medical man and would not consent to have one fetched till she was so collapsed as to be beyond any hope of recovery. Dr. Donovan, who was called in, was of opinion that her life might have been saved if she had been properly attended. The women did all they could, but "their ignorance prevented them rendering the deceased any aid." The coroner thought the case showed the necessity for passing a Midwives Bill. The jury wished to express their unqualified disapproval of the practice of persons calling themselves midwives attending at confinements. Something must evidently be done. The incompetent midwife is a source of grave danger to lying-in women.

A PROJECTED PUBLIC HOT-WATER SUPPLY.

WE alluded last week to an ingenious system of bringing a hot-water service supply within the reach of the public at the cost for a gallon of boiling water of one halfpenny. The proposal is one which demands careful attention, since if adopted it would present many points of interest from a domestic, economic, and hygienic point of view. The method consists briefly in utilising the waste heat of the street gas lamp. We will assume that this is satisfactory from the engineering point of view and free from danger. The heat is absorbed from the flames by means of a coil in which steam is generated and driven into a reservoir of water contained in a chamber at the bottom of the lamp. The hot water may be drawn off by placing a halfpenny in a slot and turning a valve. The source of heat, which is otherwise lost is thus cheap, but street lamps, of course, are not alight between sunrise and sunset in broad daylight, and during that interval the gas would have to be paid for, for heating purposes only. Gas, as is well known, is not an economic fuel for raising water to the boiling point. We take it that to ensure a continuous supply of hot water—and any failure to do so would, we imagine, be disastrous to the enterprise—those street lamps fitted with the hot-water apparatus would never be extinguished. Then occurs the question as to what the promoters intend to do where the public gas lighting is afforded by burners of a different type to the ordinary "fish-tail." For example, many of our streets are lighted with the incandescent gas burner, which, as is well known, consumes only one-half the quantity of gas consumed in a burner of plain type. The output, therefore, of heating power would be proportionally less. Again, with the regenerative burner of the Wenham type it is essential that the gas on its way to the burner should be heated automatically—that, is by the heat of the products of its own combustion. Since burners of the kind just described are largely in use for public lighting it would be interesting to know what the promoters propose to do in such cases. It cannot be doubted that the supply of hot water, especially in the poorer parts of London, would confer an inestimable boon upon the "masses." Consider, for instance, the advantage to the toiler for daily bread who has to rise in the small hours of the morning. For the comparatively small outlay of a halfpenny he could procure a gallon of hot water sufficient for the preparation of his coffee, cocoa, or tea, as well as for ablutionary and other purposes. It is proposed to extend the scheme a step further. Thus by means of automatic machines placed close to the "hot-water lamp post" the man in the street may provide himself with a cup of tea, coffee, cocoa, or even beef extract. This proposal raises a question of sanitary import. To the lamp posts are to be chained tin mugs which, supposing the movement becomes popular, will serve as a food utensil for a great number of more or less healthy people. But obviously the risk of infection could be easily lessened by each customer washing the cup out with boiling water. There is another important point which this proposal brings to mind. Assuming that the heating process is safe it is just possible that the apparatus would be liable to abuse by senseless people, in which case grave issues might ensue. The lamp post is commonly represented as a source of refuge and support to the intoxicated person; and in his endeavours to catch hold of a friendly projection, perhaps at the same time with some muddled idea that by placing a coin in the slot there was prospect of another tipple, the consequences might be serious. We hope, however, that time will prove that the apparatus is reliable and safe and of real practical value, because we believe, as we have said, that the cheap supply of boiling water will confer an inestimable advantage, especially upon the poorer classes of the community.

TOBACCO-SMOKING AND GENIUS.

IN his work entitled, *Introduction à la Médecine de l'Esprit* M. Maurice de Fleury devotes a chapter to tobacco-smoking from the point of view of men of letters. The following are the opinions in epitome of three amongst the most eminent writers of the century. In the first place Balzac: "The architect of that cyclopean monument which bears the name *La Comédie Humaine* professed a fanatical aversion to tobacco in all its forms, and was constantly employed in an endeavour to purge the *Régie*. In his books he invariably covers with contempt the characters whom he portrays as smokers, and an entire chapter in his 'Treatise on Modern Stimulants' consist exclusively of fulminations against the weed and its worshippers. His, in fine, is the motto under which the devoted members of the *Société contre l'Abus du Tabac* wage an unceasing war—'Tobacco destroys the body, attacks the intellect, and besots the nations.'" Next, Victor Hugo: "The author of *Les Misérables* was likewise no smoker. As Théodore de Banville once said, 'In the house of Victor Hugo, Peer of France, no one has ever even attempted to smoke.' In this connexion an anecdote suggests itself. One evening in the master's home one of the guests, Villiers de l'Isle-Adam, I think, was vaunting the beneficent effects of a cigarette on a creative imagination. The great poet at once rose in revolt. 'Believe me,' said he, 'tobacco is more hurtful to you than beneficial; *it changes thought into reverie.*'" Finally, M. Émile Zola: "I have no definite opinion on the question. Personally, I gave up smoking ten or twelve years ago on the advice of my medical attendant,

Digitized by Google

at a time when I believed myself to be affected with heart disease. But to suppose that tobacco exercises an influence on French literature raises a question of such magnitude that the most rigid scientific proof alone could dispose of it. I have known great writers who smoked without stint, but their intellects were not one whit less acute. If genius be a neurosis, then why seek to cure it? Perfection is such a very tiresome thing that I very often regret having broken myself of the tobacco habit. And as I know nothing more about the question I do not dare to enlarge upon it."

THE VIRTUE OF AN "IF."

IT is reported in the daily press that the Lambeth Vestry have received a letter from a firm of solicitors who state that a client of theirs, who desires to remain anonymous, is willing to contribute the sum of £10,000 towards the cost of founding a general hospital in South London provided that certain stated conditions are adhered to. The donor also makes sundry suggestions as to administration. The offer is a generous one; but £10,000, though a large sum, will not go very far towards founding a hospital; and we must confess to a desire to know a little more about the "conditions" and the "suggestions." They may be sensible—hospital management as it stands is not perfect any more than anything else in the world—or they may be of such a character as to be absolutely unworkable; that is to say, of such a kind that no medical man would, or could, serve the office of physician or surgeon while adhering to them. Anonymity in charity is to be respected; but the conditions under which the gift is offered should be published.

THE MANUFACTURE OF KOCH'S "TR" TUBERCULIN.

IN the *Medical News* (New York) of Aug. 28th is a paper by Dr. E. L. Trudeau and Dr. E. R. Baldwin, of Taranac Lake (N.Y.), on "The Need of an Improved Technic in the Manufacture of Koch's 'TR' Tuberculin." The writers state that some experience of the use of this substance has been gained by them which shows evident imperfections in its present mode of manufacture, and indicates the possibility of serious objections to its use in human beings until these shall have been overcome. Disclaiming any intention of criticising the value of the original and all-important facts bearing on the production of artificial immunity set forth in Koch's recent paper, the writers confine their present notes to that part of their experience which relates to the character of the product as at present manufactured and sold; and briefly present evidence thus far obtained which bear on the nature and defects of the preparation itself. Two facts present themselves: (1) the extreme difficulty of preventing accidental contaminations of the substance in the somewhat complicated process of manufacture without the use of heat or antiseptics; and (2) the evident uncertainty of separating by centrifugation alone the uncrushed and still living tubercle bacilli from the fluid in which they are suspended. The experience of the writers would indicate that neither of these difficulties appears to have been as yet entirely overcome by the present manufacturers; and as the first requirement of an injective fluid intended to produce immunity is that it should be entirely free from danger, they have felt it their duty to make known such of their observations as relate to this point. They have examined seventy-six vials of the new tuberculin (designated "TR"), and give a table embodying the results of their investigations. Twenty-eight of the vials were cork-stoppered, and on culture and microscopic tests all showed various yeast-like growths, but no attempts were made to identify them. Forty-eight vials were glass-stoppered, and of these, thirty-six were sterile and the others contaminated with moulds. Observations on guinea-pigs indicated that these contaminating organs were non-pathogenic, that the immunising properties of the fluid might be impaired by their growth in it, and that with a little care in the selection of sterile bottles, with the application of the culture test to each, the use of the preparation in the human subject was perfectly permissible. The possibility that the fluid contained tubercle bacilli was a much more serious matter. Repeated microscopic examinations of the various specimens received at different times were made with negative results, but on centrifugating the contents of one or two bottles at a time and examining the sediment six or eight well-stained tubercle bacilli were found in each cover-glass with little difficulty. The writers then inoculated five animals with the tuberculin; four of these remained in perfect health, but one developed tuberculosis. Experiments were then made with centrifugating the fluid at a very high speed (4000 revolutions a minute) for an hour, and even then they were not quite certain that the fluid was absolutely free from bacilli. In our issue of Sept. 18th is a paper by Mr. Frederic Eve detailing cases of surgical tuberculosis treated by Koch's new tuberculin, and he is of opinion that some slight although no markedly favourable influence may be exerted in cases of early tuberculosis of joints or in those in which no evidence of softening of caseous material exists. But the effect where caseous material has broken down, especially if the disease has become septic, is negative. Reports on the therapeutical action of this remedy differ, and not sufficient time has elapsed since its introduction to enable any definite judgment to be passed upon it.

THE SALMON CLAUSE AND APPRENTICES' INDENTURES.

ONE by one old traditions are being upset by the modern process of inquiry. The fierce light which beats upon a throne is as nothing to that which beats upon the manners and customs, whether traditional or not, of our ancestors. The last to be overturned is one that perhaps we were acquainted with from our earliest childhood, since it is referred to in that delightful book "The Water Babies," and it is this, that formerly salmon was so plentiful throughout Great Britain that it was a common practice for the indentures of apprentices and agreements with servants to contain a clause that they should not be required to partake of that fish for dinner more than a certain number of times weekly. Dr. T. N. Brushfield is the unkind person who has robbed us in the most scientific and convincing manner of this cherished delusion. We have received a reprint of a paper read before the Chester Archæological Society in which he recounted his researches into the question and brought forward evidence from various county histories, *Notes and Queries*, sundry antiquarian works and other documents to prove how widespread the belief is. He also hunted high and low for an indenture containing the said clause, but he never got nearer than the following letter from a medical man in the north of England: "In 1852 I was apprenticed to my uncle ..... and when signing the indenture the solicitor remarked to my uncle, 'This is almost a *verbatim* copy of your own indentures, with the exception of one clause which I have omitted, thinking it unnecessary at the present day—viz., he is not to have salmon more than two days a week.' My uncle was apprenticed to a surgeon in the East-end of London, and supposing him to have been bound at the age of seventeen the indenture would have been drawn up in the year 1825." Dr. Brushfield then quotes evidence to show that salmon was never very cheap at any time, and quotes an opinion of Frank Buckland that

Digitized by Google

the origin of the clause, if it ever existed, was that apprentices used to be fed upon spent fish which were both nasty and unwholesome. Dr. Brushfield thinks that the custom might have originated from a dread of leprosy; but, on the whole, he is at present unable to regard "the asserted salmon clause in the indentures of apprentices in any other light than as a myth."

TYPHOID FEVER AT KLONDYKE.

WHEN masses of people suddenly and unexpectedly congregate together in places where no adequate preparation for living has been made an outbreak of disease in some form or other is usually the result. It is not very surprising, therefore, to hear that a report from Dawson City announces that there has been an outbreak of typhoid fever in the district. If this report is correct it is to be feared that a disease of this nature will bear hardly on a population the majority of the members of which are already weakened by hardship and want of food. It is said that the medical men are well occupied and getting £40 a visit, a sum which at first sight may fairly take away the breath of some of the hard-worked and badly paid members of the profession at home. A man's wealth, however, has to be reckoned by his expenditure, and even if the magnitude of the fees be true the glamour is somewhat dulled when, on reading a little further, we find that eggs are selling for 4*s.* each, from which it may be fairly inferred that all the necessities of life, to say nothing of its luxuries, are proportionately dear.

SULPHUR BACTERIA.

PROFESSOR MANABU MIYOSHI, of whose observations on iron-containing bacteria we published an abstract in THE LANCET of Sept. 11th (p. 611), has contributed to the *Journal* of the Imperial University at Tokio, Japan, a long paper in German on Sulphur Bacteria. In 1895 he was led to examine some sulphur-encrusted organic growths (*Schwefelrasen*) found in the reservoirs and conduits of the hot springs of Yumoto, at Nikko. The water is rich in sulphuretted hydrogen, and these "growths" are formed by the sulphur of the gas separating and being deposited on a gelatinous substance of bacterial origin, which may perhaps be identical with the *barégine* of some European sulphuretted waters. Two conditions are necessary for the formation of the "growths"—(1) that the water should be constantly flowing, and (2) that it should be very shallow. The temperature of the water in which these objects had their habitat varied from about 51° to 70° C. In the rapidly-flowing water their colour varied from pale yellowish-white to almost pure white, but in the slower currents they were always yellow, the explanation being that in the latter case the sulphur was in the form of handsome, tolerably large crystals, mostly either rhombic octohedra or monoclinic prisms, whilst in the former case it was in minute amorphous particles mixed with imperfect prisms. In the slow currents the length of the *Schwefelrasen* varied from 0·5 cm. to 2 cm. (from ¼ in. to ¾ in), but in the rapid currents they might be as long as 20 cm. (8 in.). The average length was from 3 to 5 cm. (from 1¼ in. to 2 in.). The gelatinous substance is tough and slippery, and gives all the characteristic colour reactions of mucus; it contained principally cylindrical sickle-shaped colourless cells, varying in length from 6μ to 28μ, the average dimensions being 23μ in length and 1·4μ in breadth. It was very difficult to find any of the gelatinous substance free from visible sulphur deposit; even the purest sample which could be obtained showed granules of sulphur under the microscope, its comparative freedom from deposit being due to the fact that it happened to be protected from the air, whereby the oxidation of the sulphuretted hydrogen was hindered. Professor Miyoshi's experiments showed that this substance has an exceptional power of inducing a precipitation of sulphur from sulphuretted water. Samples of it placed in currents flowing from the spring, exposed to the air and having temperatures of 59° and 69° C., were covered with a layer of sulphur in a quarter of an hour or half an hour, and after the lapse of an hour the deposit was so thick that the whole was indistinguishable from the ordinary *Schwefelrasen*. Control experiments made with strips of paper and bundles of thread, as well as with bundles of thread smeared with starch paste, partially coagulated albumin, and concentrated gelatin solution or thick glue, showed that these objects when suspended in the water received a slight coating of sulphur, not in any way comparable to the thick deposit formed on the bacterial growth Up to the present time five colourless and eight coloured sulphur bacteria have been found at Yumoto. The former are *Thiothrix nivea* (Rabenhorst), *Thiothrix nivea* (Rabenhorst), new var. *verticellata*, *Thiothrix tenuis* (Winogradsky), *Beggiatoa alba* (Vauch.), and *Beggiatoa minima* (Winogradsky). The coloured sulphur bacteria may produce either a peach-red or a violet effect, the former including *Chromatium Weissii*, *Chromatium minus* (Winogradsky), *Chromatium vinosum* (Cohn), *Chromatium minutissimum* (Winogradsky), *Thioderma roseum* (new genus and species), and *Thioderma rubrum* (new species); the violet bacteria are *Thiosphaerion violaceum* (new genus and species), and *Thiosphaera gelatinosa* (new genus and species). Professor Miyoshi found that under the influence of certain solutions *Chromatium Weissii* presented the phenomenon of chemotaxis in a marked degree, the cells moving either away from or towards these solutions according to the substance which they happened to contain. For the purposes of the experiments Pfeffer's capillary tubes were used, about 1 cm. in length and 0·05 mm. in diameter at the orifice. The cells were strongly attracted by weak solutions of sulphuretted hydrogen, and by weak (from 0·3 to 0·5 per cent.) solutions of ammonium tartrate, potassium nitrate, ammonium phosphate, &c.; but, on the other hand, they retreated from a solution of malic acid, withdrawing altogether from the space represented by a sharply defined "repulsion sphere," having a diameter about forty-three times that of the capillary tube. The description of these various organisms is illustrated by a number of lithographed drawings, some of which are coloured. In the opening address in the Section of Botany at the recent meeting of the British Association at Toronto Professor H. Marshall Ward referred more than once to Professor Miyoshi's investigations on chemotaxis and allied phenomena.

THE ABUSE OF DISPENSARIES.

WE quote the following from the *Globe* of last Monday "The exceedingly mean people who, without the excuse of poverty make use of free elementary schools and free hospitals equally victimise, it appears, charitable dispensaries. While never contributing a farthing towards the maintenance of these excellent institutions they feel no shame in resorting to them for medical advice and medicine. A correspondence on this scandal which has lately been running in a Warwickshire paper reveals some cases of the sort which appear almost incredible. In one instance, the owner of a whole row of houses boasted that he always could and did obtain gratis treatment at the dispensary; all he had to do was to wear his oldest clothes. Of a similar sort was the well-to-do woman who, whenever any ailment troubled her, doffed the fine raiment she usually wore and clad herself in the most ragged garments her wardrobe contained. Letters of recommendation have to be obtained, it is true, but that can be easily managed by making pretence that the introduction is required for some poor person. Not only does this gross system of imposture help to exhaust dispensary funds, which are never too affluent, but it tells terribly against struggling medical men. When one of these declined to attend the family of a

Digitized by Google

thriving tradesman for the beggarly remuneration of 3s. 6d. a week, the answer was, 'I do not see the fun of paying half-a-crown a visit when I can get advice and medicine for nothing at the dispensary.' It appears to be quite a common practice to coerce medical men into giving their services for next to nothing by threats of a similar character, and in many cases the attempt succeeds only too well. Subscribers to the institutions should therefore exercise all possible care in complying with requests for recommendatory letters; too often they are given without the slightest inquiry."

We heartily endorse every syllable of the *Globe's* "leaderette"—a horrible word to apply to a sensible expression of editorial opinion. If subscribers to these and other medical charities would insist upon proper precaution being taken against abuse the persons for whom the benefits were designed would obtain them, perhaps as important a consummation in the eyes of the layman as that justice would then be done to medical service.

HIGHWAYMEN AND REVOLVERS

THERE would seem to be at present a wave of criminal violence passing over the country. Gangs of young ruffians perambulate the streets, and sticks, belts, to say nothing of revolvers, are freely used. The punishment for this sort of offence is not half heavy enough. Only the other day a lad who had "accidentally" wounded another was let off with two days' imprisonment—a perfectly useless sentence. There is another phase of the revolver question which deserves consideration. Many instances have occurred lately of bicyclists, especially women, being attacked and robbed or maltreated by tramps. At an inquest recently held upon a youth, aged eighteen years, who was accidentally shot by a boy, aged fifteen years, evidence was given of the enormous sale of cheap revolvers to cyclists as a means of defence. The scoundrels who attack cyclists are hardly ever arrested, and when they are the punishment for assault is ridiculously inadequate; but, all the same, the general use of revolvers must be put a stop to. The defunct Pistols Bill must be re-introduced into Parliament and passed, and the lash should be made part of the punishment for brutal assaults on the highway, whether accompanied by robbery or not.

THE ETIOLOGY OF INFECTIVE ENDOCARDITIS.

IN the *Edinburgh Medical Journal* of July, 1897, Dr. A. A. Kanthack and Dr. H. M. Tickell have published a valuable article on this subject, based on an analysis of all the fatal cases which were observed in St. Bartholomew's Hospital from January, 1890, to March, 1897, and subjected to a necropsy. These amounted to eighty-four. The writers very properly insist that the term "infective" should be used and not "malignant" or "ulcerative." The question always is, Are the vegetations due to bacteria or not? Micro-organisms may cause acute endocarditis without ulceration, and, conversely, ulceration may be found in their absence. In all but ten cases either old cardiac disease or an inflammatory infective lesion accompanied the endocarditis. Of these ten cases malignant disease existed in 4, and a possible pneumonia in 1, so that only 5 cases can be considered as uncomplicated. Old cardiac disease was present in 54 cases (64 per cent.), 16 of which were accompanied by a recognised infective process—viz., pneumonia in 7 cases, pyogenetic process in 4, empyema in 1, vaginal and uterine disease in 2, bronchiectasis in 1, and influenza in 1. Of the remaining 30 cases in which old cardiac disease was absent an infective process was discovered in 20, which either preceded or accompanied the endocarditis—viz., pneumonia in 5, pyogenetic process in 6, empyema in 1, vaginal and uterine disease in 2, otitis in 3, tubercle in 2, and typhoid fever in 1. Of all acute diseases pneumonia is most frequently complicated with endocarditis. The writers found an antecedent pneumonia in 14 per cent. of all the cases. Where the pneumonia is croupous the pneumococcus is the cause of the endocarditis, and seems to be attracted and arrested by a pre-existing cardiac lesion. Endocarditis is by no means common in typhoid fever. When it occurs, either streptococci and other pyococci or typhoid bacilli have been found in the heart's blood. Similarly, in those rare cases of infective endocarditis occurring in diphtheria or gonorrhœa, the Klebs-Löffler bacillus or Neisser's coccus may be present, or streptococci and other pyococci. In one case there was a tuberculous endocarditis. Mixed infections are common in all these cases. Therefore, when an endocarditis complicates an infective fever it may be (1) homologous, (2) heterologous, or (3) mixed infection of the endocardium.

IS OLIVE OIL A FOOD OR A DRUG?

THE Islington Vestry has lately been foiled by a decision of Mr. d'Eyncourt at the North London Police-court in a case of some importance. A young woman employed by the vestry under the Sale of Food and Drugs Act asked in a grocer's shop for a bottle of olive oil at 5½d. On being analysed it turned out to be, not olive oil, but cotton seed oil. The defence was that it was marked "Sublime salad oil," and that salad oil included cotton seed, olive, and other oils; that it was not a drug, not a medicine for internal or external use, and they were summoned for selling it as a drug. The contention of Mr. Harris, the medical officer of the vestry, was that olive oil is a drug used internally and externally. The magistrate, in deciding against the vestry, said the vestry had pinned its faith to the view that the oil was a drug, and held that it was a food and not a drug, especially considering that it was bought at a grocer's shop. If a medical man wanted to make up a prescription it is to be hoped, his worship said, he would go to a druggist and not purchase a 5d. bottle at a grocer's shop. The summons was dismissed with a guinea costs. It is a pity the vestry did not in its summons recognise that olive oil is a food as well as a drug. It is certainly a medicine, used not only externally, but in large doses internally by itself, besides entering into the composition of seventeen or eighteen preparations in the Pharmacopœia.

DIPHTHERIA AND SCHOOL ATTENDANCE.

THE report of Dr. F. J. Allan, medical officer of health for the Strand, for the eight weeks ending Sept. 11th, 1897, contained a passage of interest, bearing upon the relation of the spread of diphtheria to attendance at board schools. Dr. Allan has noticed this year, as in past years, that as soon as the school holidays begin the number of cases of diphtheria "show a decline which continues until the schools resume work, when the notifications rapidly increase." He continues as follows:—

"In this connexion I have to report the receipt of a memorandum, prepared in the Medical Department of the Local Government Board, on the circumstances under which the closing of Public Elementary Schools or the exclusion therefrom of particular children may be required in order to prevent the spread of the disease. You will probably refer it to your Health Committee with a view to taking any action thereon which they may think desirable. Statements have been freely circulated in the press lately that diphtheria has been increasing at an alarming rate during the last few weeks. I find in this district that only 4 cases have been notified so far this quarter, and on examining the returns for the whole of London for the first nine weeks of the quarter I find that the average number of cases notified per week has been 259, while in the corresponding period of last year the average was 284. I do not wish to appear as taking a light view of the amount of diphtheria which has occurred, but I would point out that so far this year there have been fewer cases notified than in 1896. Apparently, public attention has been strongly drawn in this direction by the inability of the M.A.B. to

Digitized by Google

find hospital accommodation for all cases applying for admission. It was not until the end of the year 1888 that diphtheria cases were admitted to the M. A. B. hospitals, and it is only recently that the public have begun to demand admission for this class of patient, prompted to do so doubtless by the improved results obtained in the hospitals since the antitoxin treatment was introduced. The Asylums Board has not accommodation for the patients who seek admission in increasing proportion, and from this cause apparently have arisen the statements in the papers that there was an increasing epidemic of disease at present. It is within the two months from now that diphtheria reaches its maximum in each year, and from present appearances I think it is probable that there will not be so many cases this year as last."

A DINNER TO SIR SAMUEL WILKS.

ANY old friends or pupils of Sir Samuel Wilks, Bart., who wish to be present at the dinner at the Hôtel Métropole on Wednesday, Oct. 6th, at which it is proposed to entertain him, are requested, if they have not already done so, to apply at once to the Secretary, Dr. G. Newton Pitt, 15, Portland-place, W., at the same time enclosing 22*s*., the price of a dinner ticket (including wine).

ANEURYSM OF THE INTERNAL CAROTID ARTERY FOLLOWING SCARLET FEVER.

IN scarlet fever cellulitis of the neck sometimes affects the great vessels, exposing them or causing perforation; but we know of no case like the following, in which an aneurysm of the carotid artery formed. It has been published by M. Lyot and M. Retit, and is abstracted in the July number of the *Revue des Sciences Médicales*. A girl, aged nineteen years, was attacked by scarlet fever, with severe inflammation of the throat. A month after the onset there appeared in the left sterno-mastoid region, immediately below the mastoid, a swelling the size of a walnut, reducible, pulsating energetically, and with a systolic murmur. On examining the throat the left tonsil was found pushed towards the middle line, and digital examination showed a swelling also pulsating with expansile movements. On exploratory puncture with a Pravaz syringe blood was obtained. Acute dilatation of the left internal carotid artery following acute arteritis was diagnosed. No treatment was employed. Gradual improvement took place, and the patient spontaneously recovered in three months.

A CURIOUS FOOTBALL ACCIDENT.

A REMARKABLE accident was reported in recent issues of our lay contemporaries. During a match at Hull, said the report in more than one place, one of the forwards wrenched himself and fractured a lower rib. He was carried off the field, "but resumed play afterwards, the serious nature of the injury not being realised at first. At the Manchester Infirmary it was found that the fractured rib had penetrated the kidneys, causing internal hæmorrhage." The story struck us as a very strange one. A fractured rib is not always easy to diagnose, especially in a muscular subject, and the presumption was that the laceration of the kidney occurred as a result of resuming play. The report went on to say that there was no hope of recovery. The true facts are as follows, and we think that they should be known, as the widely disseminated story reflects rather seriously upon all the unfortunate lad's comrades. To allow a person considered to have a fractured rib to go on playing, and then for no apparent reason to let him go all the way from Hull to Manchester for medical advice, would have been inhuman. The player in question was charged in the left flank by another player. He did not resume play, and his injuries were attended to by a local practitioner who advised his removal to the Hull Infirmary. The injured player, however, insisted on being taken to Manchester, where he was admitted to the infirmary after midnight. No [diagnosis was made] of fractured rib, but he was then found to be suffering from shock and extreme tenderness between the last rib and the crest of the ilium on the left side. There were also increased resistance in this site and a large quantity of blood in the urine. These symptoms, which seemed to indicate a ruptured kidney, disappeared after forty-eight hours, and hopes are now entertained of the patient's recovery.

DUCHENNE.

UNDER the editorship of Dr. Geo. Gautier there have just been published[1] the orations delivered at the inauguration of the monument recently erected at the Salpêtrière to the memory of Duchenne of Boulogne. The ceremony took place on Sunday, June 27th, under the presidency of the Minister of the Interior. It was claimed for Duchenne that in the domain of neuro-muscular pathology, of the physiology of movement, and of the therapeutic applications of electricity he had literally evolved order out of chaos. To him we owe the axiom that the nutrition of the muscle depends on the cells, or on certain cells, of the anterior cornua of the cord. His classic investigations on the nature of "the atrophic paralysis of infancy," of atrophic spinal paralysis in the adult, of progressive muscular atrophy, and of locomotor ataxy were eloquently referred to. His life had been that of a modest man of science; he had known neither honours nor rewards; he was not a member of the Institute or of the Academy of Medicine. The presence of delegates from these learned bodies on that day seemed like an expression of regret that they could not claim him as one of them. That monument and that day's celebration were not only an act of justice, but also an act of reparation.

IT is reported that medical students in Germany will not in future be allowed to visit the clinics of the German Universities unless they have passed the preliminary medical examination. Foreigners will have to pass an equivalent examination.

THE medical officer of health of Maidstone reported on Wednesday last to his sanitary authority that 306 cases of typhoid fever had been recently notified in the borough.

A MEETING of the English Branch Council of the General Medical Council will be held on Tuesday, the 28th inst., to receive the precept of the returning officer for the election of a Direct Representative in the room of Dr. R. R. Rentoul, resigned.

THE International Congress of Neurology, Psychiatry, Medical Electricity, and Hypnology, which has been held at Brussels, came to an end on Saturday, Sept. 18th, 1897.

DR. CORFIELD, who has been suffering from ptomaine poisoning during the past week, has now quite recovered.

[1] Imprimerie Brevetée, Michels et Fils.

FATAL ACCIDENT TO A MEDICAL MAN.—On Sept. 16th Dr. Strethill H. Wright, of Manor House, Ganarew, near Monmouth, was thrown from his horse whilst riding near the village of Whitchurch. He was found in an unconscious state and conveyed to the Monmouth Hospital, where he shortly afterwards died, the cause of death being a fractured skull. The deceased was educated at Edinburgh University and graduated M.B. and C.M. in 1867, obtaining the M.D. four years later and the M.R.C.P. Edin. in 1872. Dr. Wright was well known and highly respected in the neighbourhood, and leaves a widow and family for whom much sympathy is felt.

THE VACANCY IN THE GENERAL MEDICAL COUNCIL.

THE number of candidates has been increased from two to five during the week, the new names before the profession being Mr. Victor Horsley, F.R.S., Dr. T. M. Dolan, and Dr. J. A. Rigby. We publish the addresses of the first and last, but Dr. Dolan's address has not reached us, and we are uncertain from the wording of his letter (see page 813) whether his intention to stand is definite.

Dr. J. A. Rigby has received the support of an emergency meeting of the Preston Medico-Ethical Society, sixteen members out of a total membership of fifty-five having decided, we are informed by the honorary secretary, that he is "a fit and proper person to be elected as a Direct Representative."

Mr. George Jackson's candidature is being supported by the Central Council of the Incorporated Medical Practitioners' Association.

Dr. Rentoul has sent to us the following copy of a letter which he has forwarded to the President of the General Medical Council:—

"Hartington-road, Liverpool, Sept. 17th, 1897.

"DEAR SIR,—I beg to withdraw the resignation of my seat upon the General Medical Council. I have been impressed with the strong feeling that I, working almost alone, can do very little indeed to aid in carrying into effect those Medico-Political and Medico-Ethical questions which I have had at heart for a good number of years—and more especially so, as Practitioners appear to be so very slow to back up those who are working on their behalf.

"Since the announcement of my resignation I have, however, received pressing requests to remain upon the Council, and I now agree to do so for the present. Moreover, it has been pointed out by THE LANCET that my resigning now may not only deal a severe blow to a question which I have repeatedly brought up since 1890—I refer to the question of Increased Direct Representation of Practitioners upon the Council—but that it would cause the Council to spend some hundreds of pounds upon a new election.

"I sincerely hope that in the immediate future Practitioners will see it to be their plain duty to take a deeper and truer interest in Medico-Political and Medico-Ethical questions, and that those few who have tried to fight their battles and to improve our position generally will receive, not only greater sympathy, but more practical help.

"I am, Sir, yours truly,

"ROBERT R. RENTOUL."

We learn, as we expected, that it is not within Dr. Rentoul's power to withdraw his resignation. His letter does not represent accurately what THE LANCET has said.

MR. VICTOR HORSLEY'S ADDRESS.

TO THE REGISTERED MEDICAL PRACTITIONERS OF ENGLAND AND WALES.

LADIES AND GENTLEMEN,—Having agreed to present myself as a candidate for election to the General Medical Council, I feel it is perhaps necessary to explain why, having declined to be nominated at the election in November last, I have now reconsidered the position. I believed then that it was desirable that the three seats of Direct Representatives should be occupied by general practitioners, but since that date I have, in the light of full knowledge of the unfortunate result of that election, and especially of its adverse influence on the important question of increased direct representation, been driven to the conclusion that the prospect of advancing medical reform depends more upon the previous training of the representatives than upon the fact of their belonging to one particular section of the profession.

Further, a careful study of the situation shows that the Medical Acts have conferred so much power upon the General Medical Council as to render it certain that the most expeditious method of obtaining reform is to influence the Government through the Council; but to accomplish this it is obvious that an intimate personal acquaintance with the methods, laws, and procedures of the Council should be combined with a knowledge of the many pressing needs of the profession and the increasing encroachments on the legal rights, liberties, and, indeed, income of the practitioner.

I may say, I think, without exaggeration, that my work of the last four and a half years as President of the Medical Defence Union has furnished me with a training of the kind required.

Thus, as regards the official, and especially the legal, work of the General Medical Council, the conduct of the numerous and important cases placed by the Union before the Council has brought to my notice many points in medical legislation and in the procedure of the Council amendment of which is urgently necessary. Having a detailed experience of these hindrances and deficiencies I believe I could be of service to the profession in securing the removal of some of these obstructions to immediate progress.

As regards a requisite knowledge of the needs and exigencies of general practice, my official work in the Union has brought me into daily contact with applications from all branches of the profession in different parts of the country, made under the most varied circumstances, thus rendering me intimately acquainted with the difficulties and perplexities of my colleagues.

Of the questions immediately affecting the medical profession I consider the following to be the most pressing, and to require, not only consideration, but decisive treatment by the Council:—

1. The amendment of the Medical Acts, specially including—
   (*a*) The representative constitution of the Council.
   (*b*) The securing of a one-portal system of admission to the profession.
   (*c*) The suppression of irregular practice by confining practice for gain to registered persons.
2. The regulation of medical aid societies.
3. The registration of obstetric nurses.

As regards the two latter questions, the Council has reopened both by the appointment of committees to report thereon, but definite conclusions must be arrived at as soon as possible, and it would be my aim to secure prohibition in the former case of the holding of Medical Aid and like appointments as being a contravention of Section 29 of the Medical Act, 1858, and in the latter to prevent any legislative measures receiving approval unless containing ample safeguards both for the profession and the public.

In conclusion, I wish to state that had either of my friends, Dr. Woodcock and Dr. Lovell Drage, consented to be nominated I would have done all in my power to further his election. As, however, for various reasons they have both declined to come forward, I have decided to do so myself, in the hope of being able to continue and extend that work in which I have always felt the deepest interest, and which I believe I could more efficiently help forward if elected to the membership of the General Medical Council.

25, Cavendish-square, Sept. 18th, 1897. VICTOR HORSLEY.

DR. RIGBY'S ADDRESS.

TO THE REGISTERED MEDICAL PRACTITIONERS OF ENGLAND AND WALES.

LADIES AND GENTLEMEN,—At the request of a number of my fellow medical practitioners I have decided to become a candidate for the seat on the Council rendered vacant by the resignation of Dr. Rentoul.

My medical experience extends over a period of thirty-one years; at the outset I was for three years a pupil in a large club, union, and general practice, followed by the usual hospital course, and subsequently I have been engaged in general practice, for the last ten years with a hospital appointment. I can thus fairly claim to have had exceptional opportunities for becoming acquainted with the needs and wants of a general practitioner. Vast changes have occurred during that time—the old apprenticeship system, with all its faults and advantages, has been practically extinguished; the old-fashioned consulting physician is rapidly becoming a thing of the past and is being superseded by the modern specialist. The Ambulance Association has sprung up into vigorous existence—nobody can predict where it will lead to in the future; our newspapers are being flooded with medical advertisements of all sorts, many of them of a most subtle nature, appealing to the fears and hopes of the people, abounding in the most delusive statements, supported by apparently unimpeachable testimony.

I am fully aware that what I am about to say will be subject to severe criticism, but my position as an applicant for your suffrages compels me to touch on what I consider as the most pressing medical questions of the day, one of the chief of which is the advent, advance, and abuse of specialism. A medical practitioner with no special qualifications, merely in consequence of a more or less temporary or permanent connexion with a special hospital, or a special department in a hospital, becomes in his own eyes and that of the public a specialist, and thus frequently at once becomes elevated into a practitioner on quite another plane, commands enormous fees, takes away from the general practitioner cases he is or ought to be quite competent to treat, and thus by a continuation and amplification of this evil is gradually reducing the general practitioner to the position of one who has perforce to attend only on the most ordinary and every-day and unremunerative class of cases, or those whom want of means prevents from visiting these so-called specialists. An illustration will prove my meaning. A family practitioner was called to a child the other day which broke its thigh. A consulting surgeon was called in to set the fracture. While laid up in bed scarlet fever developed itself and a specialist in fevers was sent for. As one sequela of the scarlet fever suppuration of the middle ear occurred, and an aural surgeon was requested to visit the child. The child's parents were by no means well off, and the cost was a serious drain on their resources. My contention is that a well-educated practitioner should have been quite competent to attend the child in each and all of the above complaints.

If we have to have specialists the present slipshod method of attaining the distinction is absolutely indefensible and unfair. Instead of having to tout for, and hustle and push oneself into, some special hospital or other appointment, let there be a system of fair, yet stringent, tests, open to every qualified medical practitioner alike, who feels the desire, capacity, and opportunity for a certain special line of practice, which tests shall confer the right to use a certain distinctive appellation, such as ophthalmic or aural surgeon, or diplomate in obstetrics or gynæcology, much as now one can get the F.R.C.S. in surgery, the dental diploma, or the diploma in public health. If some such alternative be not adopted, and the use of the term specialist by unqualified persons be not suppressed, dire mischief is bound to result to the best interests of the medical profession, for a certain section of the outside public, ever on the alert, and unscrupulous in their methods of making money, have now seized on the term specialist, which is not interdicted and not illegal, and are now, as you all know, extensively advertising themselves as specialists in the eye, ear, hernia specialists for the cure of rupture without operation,

Digitized by Google

masseurs, masseuses, medical and other electricians, specialists in fits, in diseases of women, and, more or less, for every disease under the sun. These are all more or less parasites, originated and fostered by ourselves. Another thing that has struck me most forcibly is the reckless way in which of recent years we have taken to giving free instruction in what is called first aid in surgery, with the granting of different graded certificates to candidates after examination. This movement originated, I believe, in a class of persons quite outside of the profession—the scheme was never seriously thought out by the profession at large, was chiefly engineered by a number of the youngest and most inexperienced practitioners; and, as a result, we are now faced with the fact that a body of men has sprung into existence, certificated, uniformed, drilled, decorated (for there are a number of coveted distinctions distributed amongst them), and of a quasi-medical quasi-military status, which, I fear, in the future will become a prolific breeding ground for irregular practitioners. This would not matter much, but I find that now, in the case of any emergency arising, that the service of a medical man is not immediately sought, but one of these nondescript individuals is sent for, who uses his own judgment as to the primary treatment of the case, and decides whether he feels fully competent to tackle it or not, failing which he at last condescends to send for a qualified doctor, usually, I may say, one who so kindly gratuitously instructed him in the aforesaid duties. Truly our foes have been chiefly of our own household. Another grievance of the ordinary practitioners is the introduction of many what are denominated elegant pharmaceutical preparations, by means of which a person, instead of consulting his usual medical attendant, calls in at the chemist's and gets supplied with one of the multitudinous drugs or combinations of drugs (many of which are suggested by the best prescriptions of our best physicians) mentioned, and so counter prescribing becomes rife, and again the qualified practitioner is defrauded of his legitimate patients.

Medical men again, I find, are increasingly prone on all occasions, by a sort of vicarious almsgiving, to give their technical advice and services to charitable and often semi-charitable institutions without any adequate remuneration; this is much to be deprecated, and should as far as possible be discouraged. With regard to the question of qualified midwives my views are briefly as follows. We must approach this question from a common-sense and humanitarian point of view, and not altogether from the standpoint of what is or what is not the best for the medical profession. The great bulk of confinements are attended by women; in the army, in the workhouses all the ordinary confinements are, I believe, attended by midwives, the medical officers only being called upon in difficult cases, and the term midwife is used in the army to denote those women who attend the confinements. The term midwife is an ancient one; it is descriptive and accurate; it is firmly embedded in the minds of the people, and in my opinion it is quite futile to attempt to supercede it by the term midwifery nurse, which is inaccurate, complex, meaningless, and modern. It is quite as inaccurate as it would be to call a surgical operator a surgical nurse. On these grounds then I object to the term and would retain the old-fashioned and well-established term of midwife. Labour often comes on suddenly and unexpectedly, and from sheer force of circumstances some woman with a better nerve than common, combined with a little knowledge, is forced to act as midwife. Thus these women become known as being able to act in an emergency and are gradually forced into the position of midwives, for which ultimately they demand and receive remuneration. No amount of legislation will ever in my opinion do away with this class of midwives, it is made by process of natural selection; then if that be so, surely there can be no objection to the instruction and differentiation, if I may so speak, of a rather better and higher class of midwives, who would be calculated to supersede, or at any rate supplement, the first-mentioned class. Of course, a fully qualified medical man is essential for all cases of difficult and instrumental labour.

I may say, generally, that I am bitterly opposed to any society, whatever its name may be, that trades upon the services of medical men, using them as salaried servants and making profits out of their earnings.

To summarise, I shall, if elected, and as far as I am empowered to do by the constitution and regulations of the General Medical Council, which powers I hope to see extended:—

1. Try and suppress all mischievous, lying, suggestive, and filthy advertisements, which disfigure what should be a respectable press.
2. Try and bring the subject of specialism into a rational, fair, and equitable system, open to all qualified medical practitioners alike, and eliminated as far as possible from all taint of advertising.
3. As I consider it absolutely necessary that not a few only, but everybody, should have a knowledge of what to do in a surgical emergency, I would supersede the Ambulance Association by the enforced teaching in all schools of elementary rules to be observed in emergencies for arrest of hæmorrhage, the resuscitation of the apparently drowned, the first aid of severe injuries, and such cognate subjects.
4. I should rigorously repress and discountenance all forms of unqualified practice.
5. I should, as far as consistently could be done, reprehend the practice of gratuitous attendance upon institutions, and in lieu thereof encourage direct money benefactions to worthy institutions.
6. I would establish, as far as practicable and duly safeguarded, an Order of Midwives, who should be instructed and examined by an appropriate body of medical men, but restricted to the practice of midwifery alone, and to call in a qualified practitioner in all cases of difficult or operative labour.
7. I object to the principle of Medical Aid Societies.

Finally, I am an efficient Volunteer and an Officer in the Army Medical Reserve, all questions connected with the services would receive my most careful and impartial attention. I have no wish to dictate to the general practitioners of this country on whom devolves the election of a suitable candidate, but I do feel that if they depart from their own ranks in their search for an eligible representative they will deliver the most crushing argument against themselves that can possibly be imagined if they now, or at any future time, seek to augment their number of representatives on the General Medical Council. The fact that this is my only chance of communicating my views to my fellow practitioners must be my apology for this very lengthy and, I fear, discursive address.

If elected, I can safely say that all matters pertaining to the welfare of the medical profession shall have my earnest and unbiased attention.

I am, your obedient servant,

JAMES A. RIGBY, M.D. Lond.,
Surgeon-Captain 5th L.V.A., and Army Medical Reserve.

15, Winckley-square, Preston, Sept. 18th, 1897.

MR. VICTOR HORSLEY'S CANDIDATURE.

A meeting was held at the Memorial Hall, Manchester, under the presidency of Mr. Walter Whitehead, on Tuesday evening, Sept. 22nd, to promote the candidature of Mr. Victor Horsley for a seat on the General Medical Council.

After a few words from Dr. J. Brassey Brierley, the secretary of Mr. Horsley's Manchester committee, stating the pleasure with which Mr. Horsley's candidature had been received in Manchester, the Chairman introduced Mr. Horsley to the meeting as a man not only well known to all for his surgery, but fitted by character, disposition, and particular knowledge to represent the medical profession upon the General Medical Council.

Mr. Horsley then spoke to the meeting, taking as his text the election address which we have published above. With reference to the necessity for reform in the Medical Acts he pointed out that the preamble of the Act of 1858 was clear. It defined the position of the profession as contrasted with those of uneducated persons professing to have a knowledge of medicine. In the construction of the Act the Register was the only qualification to practice, the qualified practitioner being defined by Section 34 to be a person registered under the Act. Unfortunately, the Council had not put the law into effect in controlling the practice of medicine by (*a*) unqualified persons; and (*b*) persons who had been struck off the Register for infamous conduct, or because they had been convicted in a court of law. Mr. Horsley then dealt with Clauses 31, 32, 34, and 40 of the Acts, which confer certain privileges on registered practitioners, and pointed out that those clauses had been allowed to fall entirely into abeyance, whereas if they had been properly acted upon all unregistered persons would have been brought under the Act. Of those protecting clauses Clause 40 was the most important, but the law courts, ever since the passing of the Act, had delivered the most contrary judgments on one and the same clause. A striking instance of that they found in the cases of the persons Ferdinand and Bridgwater. In the former case the Medical Defence Union successfully prosecuted under Clause 40. The defendant alleged that he possessed a M.D., U.S.A., and subsequently was convicted of forgery. However, when the Union proceeded against a person who possessed a similar degree named Bridgwater the magistrate refused to convict, and on the case being carried to a higher court Mr. Justice Grantham took a similar view. Mr. Horsley then dealt in detail with Clause 40,[1] and pointed out that the two fundamental errors in it were, first, that it dealt with title only, and not practice, and, further, that it referred only to an individual person, whereas a good deal of quackery now was contributed by companies who could not be reached either under the Companies' Act or practically under the Medical Act. The Act must be amended to enable the Council to prosecute these people, whether individuals or companies. Mr. Horsley then referred to the question of the employment of unqualified assistants and the action of medical aid societies—matters which he considered of vital importance to the profession at large, and which he promised should have his earnest attention were he elected to the Council. He then dealt with procedure within the Council, saying it was quite clear that there must be a very substantial reform in its legal procedure. The Medical Defence Union had many documents in its office which showed that the legal advisers of the Council were not sufficiently instructed in the terms of the Medical Act as they required to be for the good of the medical profession. Having regard to the fact that the legal profession itself was so extremely well protected, it seemed to him that the reason that they had been so badly served

[1] Any person who shall wilfully and falsely pretend to be or take or use the name or title of a Physician, Doctor of Medicine, Licentiate in Medicine and Surgery, Bachelor of Medicine, Surgeon, General Practitioner, or Apothecary, or any Name, Title, Addition, or Description implying that he is registered under this Act, or that he is recognised by law as a Physician or Surgeon, or Licentiate in Medicine and Surgery, or a Practitioner in Medicine, or an Apothecary, shall upon a summary conviction for any such Offence pay a sum not exceeding Twenty Pounds.

Digitized by Google

in the past was primarily that for some reason the legal profession was not in sympathy with the medical profession and its just aspirations for the protection of honest work. He was quite conscious that there were members of the Council who were anxious for reform, but they were entirely overweighted by the legal advisers of the Council. A radical cure for the state of things which at present existed was an alteration in the constitution of the Council. It was rather interesting to observe that a reform of the constitution of the Council —that is to say, the making it a more directly representative body—was inextricably bound up with the corporation question, because it was clear that the members who represent corporate bodies could not divest themselves of the idea that they were the representatives of that body. In pointing to the means for carrying out reform in this matter Mr. Horsley said they were entitled to twice the number of direct representatives on the Council. That would give them a very considerable addition to their voting strength, and would perhaps enable them to get in the thin end of the wedge for the one-portal system.

At the close of his address Mr. Horsley answered a number of questions. He admitted that he had stated that there were sufficient consultants on the General Medical Council and that there should be more representation of the general practitioner, but, as he had stated in his address, his reason for standing was that he had special knowledge of the reforms required in the work of the Council. He expressed himself in favour of the proposition that every woman who was confined should be visited within twenty-four hours by a medical man, while he did not believe in any scheme which would entitle registered nurses to practise midwifery other than under medical supervision.

On the motion of Dr. S. Woodcock, seconded by Dr. Dreschfeld, a resolution was then adopted, with one dissentient:—

"That this meeting has heard with much pleasure the speech of the candidate, Mr. Victor Horsley, expresses its complete confidence in him, and pledges itself to do its utmost to secure his success at the election."

THE RISING OF THE FRONTIER TRIBES IN INDIA.

THE unfortunate reverse, although of a temporary kind only, sustained by one of the brigades under the command of General Jeffreys, happened at a bad time, and may possibly spread the flame of insurrection, which it is compulsory on the Government of India to extinguish with as little delay as practicable. The nation has to grieve for the loss of many brave officers and men, and the Queen has lost no time in expressing her sorrow, and her admiration at the conduct of the troops. The behaviour of the native troops—especially of the Sikhs, Goorkhas, and the corps of Guides—has been beyond all praise during the present campaign. The perusal of the numerous acts of devotion and bravery on the part of these fine fellows, some of the bravest of whom have sacrificed their lives in our behalf, arouses a glow of enthusiastic admiration. Lord Wolseley, who, to do him justice, has never been wanting in sympathy with gallantry wherever he has met with it, has been greatly impressed by the official reports of the conduct and deeds performed at Tochi by many of the native officers and non-commissioned officers and soldiers, and he is understood to be doing his best to have the Victoria Cross conferred upon some of the survivors. The intelligence that has since been received from the scene of the rising on the frontier will strengthen the Commander-in-Chief's efforts in this direction. We are confident that public opinion will recognise it as a bare act of justice to the native army and a source of pride to their British comrades that the conspicuous valour shown by soldiers of the native army should be recognised and rewarded. To return, however, to the subject of the rising of the tribesmen. We can only repeat what we have already expressed—namely, that while we have no fear about the recurrence of an Indian Mutiny or wholesale disaffection on the part of the native population, the Government of that country has nevertheless to face a difficult and most expensive undertaking, and that we are still far from nearing the end of it. Not only is the rising on a very extensive scale, but the country is full of obstacles owing to its rugged and mountainous nature, the comparative absence of roads, the difficulty or impossibility of finding water-supplies for the troops composing the various columns operating in different directions, the climatic heat at this season, the treacherous, fanatical character of the opposing tribes, and of course their intimate acquaintance with all the topographical intricacies of the mountains and valleys they inhabit. It is not until the winter begins and snow descends that the tribes swarm down into the valleys in search of pasturage for their flocks and cattle and in order to escape the rigours of the climate on the mountain plateaux, and it is consequently at that season that they can best be got at and attacked. The slight and temporary reverse that overtook General Jeffreys' brigade not only gave rise to some loss of life, but probably served, as we have said, to fan the flame of insurrection by influencing the waverers. It was, however, only what must be occasionally expected in such warfare, for it is most difficult, if not impossible, altogether to guard against such occurrences as mistaking a mountain path in the dusk, and the sudden and unexpected appearance of hordes of native tribesmen. The effect of the check, however, was of a very temporary nature and was soon neutralised by the successful action of the general and his brigade that almost immediately followed it. The night attacks on our posts and camps, too, are peculiarly harassing. Nothing is more remarkable than the stealthy, cat-like way in which the tribesmen make, and conceal, their approach preceding their sudden "rushes." Transport, stores, ammunition, field hospitals, and, in short, all the arrangements for a serious expedition on a big scale are being made and by now are approaching completion. Sir William Lockhart, whose experience of like warfare on the north-west is very great, will soon be ready to assume the supreme command. It is necessary to deal with Asiatics with the utmost promptitude, but it is still more essential in Asiatic warfare to sustain no reverse, and every arrangement must be completed before advancing in full strength for following up blow by blow upon the enemy.

People in this country have but little idea of the enormous number of native followers and of the very large amount of animal transport, for none of a vehicular kind is practicable, that are required for an Indian expedition of this kind. The strain on the medical service must be great at head-quarters in Simla at the present time and the duties of the medical officers in the field of a very arduous character. The organisation of a field hospital system and of medical matters generally has, however, been placed on a much simpler and better footing than it was at the commencement of the last Afghan wars. So far as we can learn the health of the troops is good, and nothing could be better than their spirit and bearing. It was reported that cholera had broken out in the Hyderabad contingent on its way to the front and that the contingent had been halted at Aligarh, but this is, of course, a very great distance from the scene of the frontier operations, and the occurrence is consequently without any significance as regards the expedition. It must always be borne in mind that this Indian frontier revolt is, after all, but an acute exacerbation on a bigger scale of a chronic and local trouble which the Indian Government can assuredly, and will, bring to a successful end. The latest intelligence—for the current of events is now moving rapidly—shows that the blows inflicted on the Mahmunds by General Jeffreys' brigade are compelling their submission. The two converging lines of the British advance under Generals Elles and Blood have already joined hands, and promise to settle the opposition north of the Khyber Pass. The intended expedition against the Afridis and Orakzais which is soon to follow under Sir William Lockhart will, we have every reason to hope and believe, inflict a severe lesson on those strong and turbulent tribes. It seems to be quite likely that the ultimate result of this campaign may be to bring about a far more satisfactory and peaceful state of things on the frontier than has hitherto been the case.

THE DEVON AND EXETER HOSPITAL.—The Hon. Mark Rolle has recently offered £500 to the Devon and Exeter Hospital on condition that a sufficient sum be raised to clear the debt of £2000. This offer is only open to Oct. 1st, and it is to be hoped that the amount required will be raised.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6615 births and 3909 deaths were registered during the week ending Sept. 18th. The annual rate of mortality in these towns, which had declined in the five preceding weeks from 29·5 to 19·4 per 1000, further fell last week to 18·5. In London the rate was 16·1 per 1000, while it averaged 20·2 in the thirty-two provincial towns. The lowest rates in these towns were 10·7 in Cardiff, 10·9 in Swansea, 12·0 in Croydon, and 13·1 in Halifax; the highest rates were 25·8 in Preston, 26·1 in Sunderland, 28·4 in Norwich, and 29·8 in Salford. The 3909 deaths included 721 which were referred to the principal zymotic diseases, against 1272 and 945 in the two preceding weeks; of these, 454 resulted from diarrhœa, 64 from whooping-cough, 54 from "fever" (principally enteric), 53 from measles, 49 from diphtheria, and 47 from scarlet fever. The lowest death-rates from these diseases were recorded in Plymouth, Swansea, Halifax, and Bristol; and the highest rates in Salford, Hull, Wolverhampton, and Preston. The greatest mortality from measles occurred in Wolverhampton and in Preston; from "fever" in Norwich; and from diarrhœa in Wolverhampton, Salford, Preston, Hull, Sunderland, and Gateshead. The mortality from scarlet fever and from whooping-cough showed no marked excess in any of the large towns. The 49 deaths from diphtheria included 35 in London, 2 in West Ham, 2 in Wolverhampton, and 2 in Liverpool. No fatal case of small-pox was registered during the week either in London or in any other of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of last week was 3653, against 3448, 3528, and 3579 on the three preceding Saturdays; 376 new cases were admitted during the week, against 356, 371, and 376 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 116 in each of the two preceding weeks, were 113 last week, and were 47 below the corrected average. The causes of 49, or 1·2 per cent., of the deaths in the thirty-three towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Cardiff, Manchester, Bradford, Hull, and in thirteen other smaller towns; the largest proportions of uncertified deaths were registered in Nottingham, Liverpool Salford, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·1 and 18·3 per 1000 in the two preceding weeks, further rose to 19·4 during the week ending Sept. 18th, and was 0·9 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15·3 in Perth and 18·1 in Aberdeen to 21·7 in Paisley and 22·8 in Greenock. The 579 deaths in these towns included 58 which were referred to diarrhœa, 17 to whooping-cough, 9 to "fever," 8 to diphtheria, 5 to measles, 2 to scarlet fever, and 2 to small-pox. In all, 101 deaths resulted from these principal zymotic diseases, against 127 and 98 in the two preceding weeks. These 101 deaths were equal to an annual rate of 3·4 per 1000, which corresponded with the mean rate last week from the same diseases in the thirty-three large English towns. The 58 fatal cases of diarrhœa showed a slight further decline from the numbers recorded in recent weeks, and included 22 in Glasgow, 12 in Edinburgh, and 7 in Dundee. The deaths from whooping-cough, which had declined from 23 to 15 in the three preceding weeks, rose again to 17 last week, of which 7 occurred in Glasgow, 5 in Dundee and 3 in Greenock. The deaths referred to different forms of "fever," which had been 4 and 5 in the two preceding weeks, further rose to 9 last week, of which 8 were registered in Glasgow. The 8 fatal cases of diphtheria also showed a further increase upon those recorded in recent weeks, and included 3 in Edinburgh, 2 in Glasgow, and 2 in Dundee. The 2 deaths from small-pox were registered in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 69 and 78 in the two preceding weeks, further rose to 96 last week, and exceeded by 41 the number in the corresponding week of last year. The causes of 26, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·1 and 22·4 per 1000 in the two preceding weeks, rose again to 23·9 during the week ending Sept. 18th. During the past eleven weeks of the current quarter the death-rate in the city has averaged 23·4 per 1000, the rate during the same period being 20·1 in London and 18·3 in Edinburgh. The 160 deaths registered in Dublin during the week under notice showed an increase of 10 upon the number in the preceding week, and included 28 which were referred to the principal zymotic diseases, against 33 and 28 in the two preceding weeks; of these 13 resulted from diarrhœa, 6 from "fever," 5 from whooping-cough, 3 from diphtheria, and 1 from scarlet fever. These 28 deaths were equal to an annual rate of 4·2 per 1000, the zymotic death-rate during the same period being 2·3 in London and 3·0 in Edinburgh. The 13 fatal cases of diarrhœa, showed a further decline from the numbers in recent weeks, but the 6 deaths referred to different forms of "fever" exceeded the number recorded in any week since February last. The 5 fatal cases of whooping-cough also showed an increase upon those registered in recent weeks. The fatal cases of diphtheria, which had been 4 and 3 in the two preceding weeks, were again 3 last week. The 160 deaths in Dublin last week included 35 of infants under one year of age and 38 of persons aged upwards of sixty years; the deaths of infants showed a further decline, while those of elderly persons exceeded the number recorded in any recent week. Ten inquest cases and 8 deaths from violence were registered; and 60, or more than a third, of the deaths occurred in public institutions. The causes of 15, or more than 9 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-CAPTAIN WHITLEY B. STOKES, half-pay, resigns his commission. Brigade-Surgeon-Lieutenant-Colonel Holmes is appointed to the Medical Charge of the 31st Regimental District. Brigade-Surgeon-Lieutenant-Colonel Fawcett embarks for Bombay in the *Simla*, taking out the 1st Grenadier Guards to Gibraltar. He will be assisted by Surgeon-Major Kilkelly, senior medical officer of the battalion. Surgeon-Captain Wright embarks for Malta. Surgeon-Colonel T. O'Farrell resumes the post of Principal Medical Officer of the Home District.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Captain H. Bennett has delivered over Medical Charge of the Ahmedabad Central Prison and Surgeon-Captain Faichnie, A.M.S., has received Medical Charge of that institution. The following officiating appointments have been made:—2nd Bombay Lancers: Surgeon-Lieutenant Strange to the Officiating Medical Charge, vice Surgeon-Captain Jackson, transferred. 3rd Bombay Light Cavalry: Surgeon-Lieutenant King to the Officiating Medical Charge, vice Surgeon-Captain Cleveland. 7th Bombay Infantry: Surgeon-Captain Donovan to the Officiating Medical Charge, vice Surgeon-Major Jervis. 9th Bombay Infantry: Surgeon-Captain Gabbett to the Officiating Medical Charge, vice Surgeon-Major Willis. The under-mentioned medical officers have been detailed for duty with the Field Hospitals proceeding to Rawalpindi with the 2nd and the 3rd Malakand Reserve Brigade:—23rd British Field Hospital: Army Medical Staff—Surgeon-Major Addison, Captain Slayer, Captain Read, and Captain Lewis. 24th British Field Hospital: Army Medical Staff—Surgeon-Major Yourdi, Major Berryman, Captain Austin, and Captain Marder. No. 62 Native Field Hospital: Surgeon-Major Willis, 9th Bombay Infantry; Surgeon-Captain Hudson, 2nd Bombay Grenadiers; Surgeon-Captain H. Bennett, I.M.S., 4th Bombay Rifles; and Surgeon-Lieutenant R. H. Price, Poona District. No. 63 Native Field Hospital: Surgeon-Lieutenant-Colonel Barren, Bombay Sappers and Miners; Surgeon-Captain V. B. Bennett, 13th Bombay Infantry; Surgeon-Lieutenant A.

Digitized by Google

Hooton, Poona District; and Surgeon-Lieutenant H. A. Knapton, officiating 23rd Bombay Rifles. No. 46 Bombay Native Field Hospital: Surgeon-Captain Cleveland, 3rd Bombay Light Cavalry. Surgeon-Captains Vickers and Wright have been posted to the Poona District.

NAVAL MEDICAL SERVICE.

The following appointments have been notified:—Staff-Surgeons: Arthur S. Nance to the *Pearl;* John J. Dinnis to the *Collingwood;* and John Moore to the *Mohawk*. Fleet-Surgeon Charles E. Gedding to the *Haulbowline*. Surgeons: Francis J. Barter to the *Heron;* Oswald Rees to the *Jackdaw*.

VOLUNTEER CORPS.

Rifle: 2nd (Angus) Volunteer Battalion the Black Watch (Royal Highlanders): Surgeon-Lieutenant R. Grant, to be Surgeon-Captain. 1st Volunteer Battalion the King's Own (Yorkshire Light Infantry): Surgeon-Lieutenant William Henry Hender Bennett, M.B., resigns his commission, and is appointed Second Lieutenant; Samuel Lee Potter, gent., to be Surgeon-Lieutenant. 24th Middlesex: Surgeon-Lieutenant A. Eddowes, M.D., to be Surgeon-Captain.

ERYTHREAN SICK AND WOUNDED AT NAPLES.

A recent number of the *Giornale Medico del Regio Esercito* contains an interesting report by Dr. J. Alvaro, Lieutenant-Colonel in the Italian army, on the sick and wounded soldiers belonging to the forces employed in Africa who were admitted to the military hospital at Naples during the period from the beginning of March to the end of August, 1896. The total number of patients treated was 1647, their disabilities being classified as follows: medical, 826; surgical, 590; ophthalmic, 47; venereal, 171; under observation, 13. Of these, 988 cases were discharged cured and 146 were sent to their homes on leave, the remainder being disposed of in the following manner: invalided, 66; transferred to other hospitals, 313; died, 38; remaining under treatment on Sept. 1st, 96. The wounded, who numbered 419 in all, were arranged in the following order: visceral contusions and "commotions," 13; wounds from sharp weapons, 67; contused wounds, 14; gunshot wounds, 306; dislocations, 11; fractures, 8. Amongst the wounds inflicted by sharp weapons there were 28 cases of injury to the organs of generation, the parts having been completely excised close up to the pubes in no fewer than 24 instances. The chief difficulty in treating these unfortunate victims of savagery lay in maintaining a patent urethra. V-shaped incisions round the retracted orifices gave the best results, but in all cases sounds have to be worn more or less permanently. The number of men injured by "cold steel" strikes the author as exceptionally high in proportion to the total, seeing that of recent years wounds thus sustained have exhibited a constant tendency towards diminution. With regard to what may, perhaps, be styled civilised warfare this statement is no doubt correct, but where savages are concerned spears, swords, and assegais are still favourite weapons, and punctured or incised wounds must always be expected. Some of the cases related in detail by Dr. Alvaro are noteworthy. A man who had received a gunshot wound of his thigh on a level with the great trochanter remained lame and a sufferer from excessive pain extending down to the knee. It was thought that the external cutaneous nerve had become implicated in the cicatrix, which was accordingly laid open and carefully re-united by interrupted sutures. Cure was complete. A soldier sustained a gunshot wound of his forearm in the posterior aspect of the middle third, and directed from above downwards and from behind forwards. There was no aperture of exit, and neither at Massowah nor Naples could the locality of the projectile be determined. The wound had healed rapidly, but pronation and supination were both greatly interfered with. Under these circumstances recourse was had to the Roentgen rays, when at once the situation of the foreign body was made manifest. An operation promptly followed with the best results, the long-sought missile being found lying on the interosseous ligament. In another case the victim must have been endowed with an exceptional amount of recuperative vitality. A bullet entered his side about one and a quarter inches below the ribs, and, having traversed the ilium, made its exit in the upper part of the sacral region. There was a stercoral fistula at the aperture of entrance, and on examination through that of exit it was found that the subjacent bone was extensively shattered. In addition to this formidable injury the unfortunate patient had also sustained incised wounds of the nick the nose, the temporal and occipital regions, the knee, and the forearm. An operation for the fistula was projected, but the usual antiseptic treatment having meanwhile been adopted the wound of entrance closed of its own accord and the man was invalided.

SOME MILITARY APPOINTMENTS.

The appointment is officially announced of General Sir William Lockhart as Commander-in-Chief in India, in succession to General Sir George White, who, as soon as his services can be spared in India, will return to this country and take up the post of Quartermaster-General. Sir William Lockhart, who belongs to the Indian Army, in addition to his distinguished services and military reputation, is regarded as a very able, straightforward officer, and is deservedly popular with all branches of the military services. Sir George White, V.C., succeeds Sir Evelyn Wood, V.C., as Quartermaster-General, and as, *ex-officio*, President of the Army Sanitary Committee is brought into connexion with questions affecting the sanitary medical requirements of the army.

THE RECALL OF INDIAN MEDICAL OFFICERS.

All leave in the Medical Service in India is closed, and the officers at present in this country are being, if they have not already been, recalled.

The *Broad Arrow* says: "In the combined examinations for first commissions in the Army Medical Staff and Indian Medical Service, the successful candidates will, without the necessity of previously recording their names for either establishment, be allowed in future to exercise their choice as to which Service they prefer in the order of precedence that they may have obtained upon the list. Their selection will, however, in the case of the Army Medical Staff, be subject to the special regulations already applicable to entry for that service."

The Queen has conferred the Jubilee Commemoration Medal upon Surgeon-Captains V. Matthews, T. H. Openshaw, and H. D. Buss, and Surgeon-Lieutenant J. R. Whalt, officers of the Volunteer Medical Staff Corps.

A revised edition of the Regulations for the Army Medical Service has been published.

Correspondence.

"Audi alteram partem."

"THE ELECTION OF A DIRECT REPRESENTATIVE ON THE GENERAL MEDICAL COUNCIL."

To the Editors of THE LANCET.

SIRS,—It may be for your convenience and that of the profession generally that I should inform you at the earliest opportunity that the President of this Council having referred to its legal advisers a communication he received from Dr. Rentoul on the 18th instant, the opinion has been definitely given that the withdrawal of his resignation therein intimated is inoperative, and that there must be an election as already arranged.

I am, Sirs, yours faithfully,
H. E. ALLEN, Registrar.

General Medical Council Office, 299, Oxford-street, London, W., Sept. 22nd, 1897.

To the Editors of THE LANCET.

SIRS,—The auspicious advent of Mr. Victor Horsley, F.R.S., M.B., M.S. Lond., and F.R.C.S. Eng., as a candidate to fill the vacancy caused by the retirement of Dr. R. R. Rentoul from the General Medical Council should be the subject of much satisfaction to the whole profession, and it offers an opportunity of retrieving in some measure the result of last year's election. In Mr. Victor Horsley we have a star of the proper magnitude, a young, brilliant, and eminent surgeon of high social position and of means, which guarantee the quality of "stay" so desirable in one who aspires to the responsible office he has expressed his willingness to fill.

I trust the other candidates already in the field will at

Digitized by Google

once, though, of course, at much personal sacrifice of their laudable ambition, magnanimously withdraw in his favour, and thereby prove in the most convincing manner the sincerity of their expressed regard for the honour and dignity of the profession. I would venture, moreover, to deprecate any renewed attempt to confuse or endanger the issue of the election by dragging in the name of either of the deeply respected and lately retired members who have deservedly been rewarded by the presentation of the gold medal of the British Medical Association and the LL.D.-ship of the leading university of Canada. Let them now rest in kindly peace. In Mr. Victor Horsley surely we have the right man for the present occasion, and now is the hour to secure his triumphant election.

I am, Sirs, your obedient servant,

JOHN INCE, M.D. ST. AND.,
H.M.'s Indian Medical Service (retired).

Swanley, Kent, Sept. 20th, 1897.

To the Editors of THE LANCET.

SIRS,—In view of the forthcoming election for the vacant seat on the General Medical Council I would recall to mind the old views of Mr. Nelson Hardy, as printed in a letter in the *Provincial Medical Journal*, Aug. 2nd, 1886. I do not bring it forward to emphasise his change of view, but because he has so well expressed the general feeling of general practitioners and my own views. He then said: "I trust no one will suppose that I wish to dictate to others if I express my belief that it will be unfortunate indeed if the general practitioners of England cannot find men of their own class to represent them in the Council, men of sterling honesty and straightforwardness, men not to be moved from their purpose by the presence at the same Council table of those who while in regard to practice they are fully regarded as leaders in medicine and surgery in matters of medical politics have too generally constituted to make the Medical Council the failure which it has been in the past."

I would also recall to mind the words of the late Sir Andrew Clark, who wrote in the same year as follows: "Now that the interests of consultants and of teachers, of corporations and of universities, of the Crown and of the people are already more than adequately represented on the General Medical Council, and that the right of direct representation therein has been conceded to the repeatedly renewed claims of the general practitioner, it seems both natural and proper that they should themselves exercise the suffrage in their own behalf, that they should select as their own representative genuine working members of their own body. If this principle of election is disregarded, and if the representatives are chosen from outside the body of general practitioners, it will seem, at least to me, that the fight has been fought and the battle won in vain." Nothing that has occurred justifies, in my opinion, any change in our representation. There are 14,000 general practitioners in England and Wales, and surely they ought to be able to find one suitable candidate amongst them. I have been nominated, as you will see by the enclosed paper, by nearly all the medical men in Wigan, and I have received letters from influential men in different parts of the country all promising me votes and active support. I have been asked to retire in favour of Mr. Victor Horsley by a few of his friends. I do not desire a contest. I am quite willing to withdraw in favour of a suitable candidate who is a general practitioner if we can agree upon one, but I certainly must decline in any way to favour the candidature of Mr. Horsley for the reasons mentioned. I think most consulting surgeons will recognise the equity of my contention.

I am, Sirs, yours very truly,

THOMAS M. DOLAN, M.D. Durh., J.P.,
Member of Council, B.M.A.; President Elect, Yorkshire Branch, B.M.A.

Halifax, Sept. 20th, 1897.

*** Dr. Dolan encloses with his letter a copy of his nomination paper signed by sixteen of the thirty-six practitioners whose names are given in the Medical Directory as resident in Wigan.—ED. L.

To the Editors of THE LANCET.

SIRS,—All other things being equal, I think there is no doubt we should give the preference to a general practitioner as our representative on the General Medical Council. The candidature, however, of Mr. Victor Horsley must not be considered by the profession from a consultant's point of view. Although it is well known to many practitioners, yet it is hardly universal knowledge that the good work done during the past few years by the Medical Defence Union has been mainly due to the zeal and application of its president, Mr. Horsley. To those who are not fully acquainted with the routine work of the Union I would explain that its officers are brought into close contact with all sections of the profession throughout the United Kingdom. They become intimately acquainted with the various difficulties and dangers of a general practitioner's life; they possess full knowledge of the ever-recurring disputes that arise between the profession and public bodies; they become conversant with the various forms of quackery; and, moreover, they know the difficulties of suppressing it. Bearing all this in mind, I for one unhesitatingly assert that there is no general practitioner in the country who possesses a fuller knowledge of, or has a greater sympathy with, the lot of the family medical man than the present President of the Medical Defence Union. That Mr. Horsley has studied the Medical Acts and that he has kept himself *au courant* with the proceedings of the General Medical Council is common knowledge. That he has by his persistency succeeded in getting the Council to take up certain cases of "infamous conduct" is, however, not so well known.

I am, Sirs, your obedient servant,

T. GARRETT HORDER.

Windsor-place, Cardiff, Sept. 17th, 1897.

To the Editors of THE LANCET.

SIRS,—The morning paper announces that Dr. Rentoul has withdrawn his resignation of membership of the General Medical Council. Surely, if it is true it is too late to have any effect now that the President has issued notices for a new election. May I ask my medical brethren seriously to consider the present position of affairs before promising their votes. The election of Dr. Rentoul showed clearly that there is a spirit of dissatisfaction in the profession at the little power the General Medical Council possess to remedy the numerous grievances of the local practitioners. Dr. Rentoul has shown in many ways, and especially by his uncertainty of mind, that he is not the man to obtain for the profession that attention to their wishes from the General Medical Council or the Government which they expected. As there are two metropolitan members already on the Council for England, it would naturally seem right to have a provincial practitioner to fill the vacancy, and if Sir W. Foster or Mr. Wheelhouse could be induced to stand, either of them would have influence to make the wants of the profession listened to and considered. If not, I would suggest Mr. Victor Horsley as a gentleman who has proved by his management of the Medical Defence Union that he is a good business man, and having experience of the trials and difficulties of the medical practitioners would admirably represent us on the Council. His connexion with the Medical Defence Union would have to be severed, but it seems to me, as I have watched his control of that Union, that he would prove a living power on the General Medical Council by his moderation and sound common sense.

I am, Sirs, yours faithfully,

A PRACTITIONER OF FORTY YEARS' STANDING.

Sept. 20th, 1897.

THE TWELFTH INTERNATIONAL MEDICAL CONGRESS.

To the Editors of THE LANCET.

SIRS,—Many of the British members desire to send letters of thanks (through the British ambassador) to H.I.M. the Czar for the very gracious hospitality shown to them by His Majesty, and to the president and committees for their great kindness. Any member wishing to have his signature added is requested to forward his name to Dr. R. Caton or to myself.

I am, Sirs, yours faithfully,

4, Gloucester-place, Portman-square, W. JOHN LOWE.

"HONOUR TO WHOM HONOUR IS DUE."

To the Editors of THE LANCET.

SIRS,—In the admirable historical dermatological address by Mr. M. Morris at Montreal on the occasion of the

Digitized by Google

British Medical Association meeting I notice he has omitted to mention a name which some of the old practitioners of the present Victorian era will, I am sure, remember with respect—viz., that of the elder Startin, who was the first who taught and lectured on dermatology, and whose forty lectures are published in the *Medical Times* of London of 1845-46, and which lectures, I believe, were attended by the late Sir Erasmus Wilson, Dr. Tilbury Fox, and Mr. Jonathan Hutchinson, Mr Waren Tay, and other eminent dermatologists and practitioners at the time.

I am, Sirs, yours faithfully,

Harley-street, W., Sept. 22nd, 1897. JAMES STARTIN.

"AN IMPROVED ŒSOPHAGEAL PROBANG."

To the Editors of THE LANCET.

SIRS,—I understand that in THE LANCET of Sept. 18th, is a notice of an improved œsophageal probang, with illustrations. May I remind you, in fairness to myself and Messrs. Arnold, that on Jan. 9th this year you kindly published a notice and illustration of an improved œsophageal probang designed by me, and carried out by Messrs. Arnold, which embodied the improvements claimed by this later one; that is, that it is capable of being passed down the gullet without opening the bristly umbrella, and that when it has gone sufficiently far finger and thumb (of the same hand which passed it) release the catch, push down the catheter, and pull out the whole apparatus, now expanded.

I am, Sirs, yours faithfully,

E. MANSEL SYMPSON, M.D CANTAB., M.R.C.S. ENG.

James-street, Lincoln, Sept. 21st, 1897.

A QUESTION IN ORTHOGRAPHY.

To the Editors of THE LANCET.

SIRS,—In your last issue (THE LANCET, Sept. 18th, 1897) Dr. A. E. Wright communicated a paper on "A Simple Method of Measuring the Alkalinity of the Blood" which depends upon that system of chemical analysis known as "Alkalimetry." The application of this method to blood Dr. Wright calls "hæmalkimetry"; that is, he drops two fundamental letters, "al," between the "k" and "i." But whence does Dr. Wright derive "tritrate," a word I am confident has not been seen in print before? He cannot mean "triturate," it is certain. Gay-Lussac, the great French chemist, was the founder of volumetric analysis, alkalimetry, &c., and he called it "titrimetry," doubtless from the French word "titre," a standard or measure. The German verb to titrate is similarly "titriren."

I am, Sirs, yours faithfully,

CHEMICUS.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Annual Inspection of Corporation Hospitals.

THE members of the Hospitals Committee of the City Council made their annual inspection of the city hospitals on the 10th inst., under the guidance of Dr. Clarke, the chairman of the committee. The Port Sanitary Offices at the Pier Head were first visited. Here the new mortuary is situated, the erection of which was due to the persistent representations of Mr. F. W. Lowndes to the local authorities. Mr. Lowndes left no stone unturned until the disgraceful condition of things under which post-mortem examinations were formerly made were finally done away with; the latter are now made with comfort and decency, and the building is in every way creditable to the health authorities. The City Hospital South, which has been considerably improved, was next visited. The committee were shown round the building, special attention being directed to the provision for convalescent patients. Park Hill Hospital, where small-pox patients are received, afforded the visitors much delight, the charming aspect of the site enhancing the comfort of the general arrangements, which are in every way admirable. Luncheon was served at this institution. Mill-lane Hospital, Old Swan, which since its erection by the Old West Derby and Wavertree local boards has been considerably enlarged, was also visited. The last to be inspected were the Priory-road and Netherfield-road Hospitals, the latter of which is the most complete of the City Hospitals. The arrangements everywhere were acknowledged by the visitors to be highly satisfactory and afforded them much gratification and instruction.

Hospital Saturday in Bootle.

The result of the Hospital Saturday collections in Bootle and district in aid of the Bootle Borough Hospital show a falling off as compared with last year. The total receipts amounted to £257 16*s.* 2*d.*, or £22 less than last year. The falling off was altogether due to the inclement weather prevailing at the time of the collection.

Liverpool and the Manchester "Effluent."

It is not at all probable that the Bill which it is the intention of the Manchester Corporation to promote in Parliament relating to the discharge of Manchester sewage into the Mersey will proceed unchallenged. The two corporations in Liverpool concerned in the matter are the Dock Board and the City Council, the first of which deals with the navigation of the river and the latter with the sanitary condition of the port. Now it is not at all certain, even if the Manchester sewage be chemically treated, that it would not still be charged with deleterious matter. Besides, if a high standard of purification were fixed, its enforcement, in spite of heavy penalties, would always be a matter attended with difficulties. As far as the Dock Board is concerned, it is also open to doubt whether the Manchester effluent would not sooner or later affect the navigation of the Mersey. Altogether the subject bristles with difficulties and appears to excite much unfavourable comment in the local press.

Presentations to Dr. John Robertson and Dr. J. H. Chapman.

Dr. John Robertson, late medical officer of health of St. Helens, has been the recipient of a specially made table and writing-case subscribed for by the officials of St. Helens Corporation with all of whom he was deservedly popular. The many friends of Dr. J. H. Chapman, who recently resigned the medical superintendence of the Mill-road Infirmary owing to ill-health, have presented him with a testimonial and a cheque for £250 prior to his departure for South Africa as a mark of esteem for his many good qualities.

Liverpool Medical Institution.

The President (Dr. Caton) will deliver the inaugural address at the opening of the fifty-eighth session on Oct. 7th, after which he will entertain at the institution the members and associates to supper which will be followed by a smoking concert. The annual dinner of the society will take place at the Exchange Hotel on Saturday evening, Nov. 6th; the chair will be taken by Dr. Caton.

Sept. 22nd.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The late Mr. Gilbert Ward, F.R.C.S. Eng.

THE Thomas Knight Memorial Hospital at Blyth was last week the scene of a very interesting ceremony, when a bust of the late Mr. Gilbert Ward, of Blyth, was unveiled by the Right Honorable Sir M. White Ridley, M.P. The bust was executed at Venice, by Antonio Frilei, and is an excellent likeness. Mr. Ward took a great interest in the Knight Hospital, as indeed he did in all the Blyth institutions, and it was mainly owing to his exertions that the hospital was built. Mr. Ward was one of the best known and respected of the inhabitants of Blyth—he lived in the town, and practised as a medical man for sixty years, and died a few years ago, aged ninety years.

The Extra Arts Examination at Durham.

The lamentations over the result of this examination just concluded at Durham are both loud and deep. Forty-seven candidates entered their names, of whom four failed to put in an appearance, fourteen passed, and twenty-nine were rejected. The rejections at this examination are always very heavy, but it is a long time since such a result as this—only fourteen candidates succeeding in satisfying the examiners out of forty-three examined. If the Durham Extra Arts Examination be a correct criterion, school education would seem to be in a most unsatisfactory condition. It

Digitized by Google

would be interesting to hear what schoolmasters have to say about this students' bugbear the Extra Arts Examination at Durham.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Cork-street Fever Hospital, Dublin.

THE committee of management of this old-established hospital have recently presented their ninety-third annual report to the governors and subscribers. They had hoped, as stated, that on the cessation of the small-pox epidemics of the previous years, and after the crowded state of the wards during the last four years, they would have been able to report a period of comparative rest, but the contrary has been the case, and the time under review has witnessed a greater number of admissions than in any previous year, no fewer than 2632 patients having been treated. The increase of cases, it is noted, was caused by a considerable epidemic of scarlet fever, joined with smaller epidemics of measles, while there has been a most unusual recurrence of typhus fever, once so formidable in Dublin. The new convalescent home in connexion with the hospital, and situated at Glasnevin, has at present accommodation for only thirty patients. The house can, however, be enlarged, and the site, which occupies twenty acres, is quite suitable for the erection of additional buildings. It is at present the only convalescent home in Ireland for infectious cases.

Hospital Vacancies.

Mr. W. G. Mackenzie has resigned the surgeoncy to the Belfast Hospital for Sick Children. As a result Dr. Kirk will be promoted to the visiting staff, and for his post of assistant surgeon there are already several candidates in the field. The appointment of assistant gynæcologist to the Royal Hospital has become vacant through Dr. Woods' resignation on his leaving Belfast. His successor will be chosen by competitive examination on Oct. 9th.

Sept. 21st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Dangers in Operations for Exophthalmic Goitre.

M. PONCET, of Lyons, has reopened this important question before the Academy of Medicine. Hitherto very contrary opinions have been given on the matter and those, too, from observers most competent to decide the question, such as M. Pean, M. Doyen, and M. Jaboulay. M. Pean considers that it is in nowise an exaggeration to maintain that no surgeon should operate on the thyroid gland in a case of exophthalmic goitre without having very seriously considered the advisability of interfering. Professor Tilleaux considers that only spurious cases of exophthalmic goitre should be operated on—that is to say, those benign tumours of the thyroid gland which cause secondary troubles of Graves's disease sooner or later by compression of the cervical sympathetic. Such cases ought to be considered as ordinary goitres and treated as such. M. Poncet is of opinion that such a degree of caution is exaggerated in cases of simple exophthalmic goitre where the classical triad of symptoms is present from the first. Like M. Pean, or perhaps even more so, he considers that medical treatment should be relied upon for as long as possible—that is to say, until suffocation is imminent; and even then, before interfering with the thyroid body itself, an attempt should be made to give relief by a simple incision through the soft parts in front of the tumour. In all cases of Graves's disease medicinal treatment should be tried first, and continued even though amelioration be slow, in patients who are in a position to undergo the restrictions imposed by the treatment. In those patients who cannot do this, or who become rapidly cachectic or relapse after a temporary improvement, operation should be advised before the general health becomes too much impaired; but both the patient and his friends should be told that there are risks to be run. If the tumour is of medium size either complete enucleation should be performed or a partial thyroidectomy; if the growth is very large and vascular exothyropexy should be performed, despite the chance of failure. Excision can always be resorted to as a secondary measure when a partial thrombosis of the vessels has been set up by exposure to the air, thus diminishing the operative difficulties and the danger of intoxication. As regards the class of thick, fleshy tumours or cases of Graves's disease without a goitre or only a very small one and where the vaso-motor troubles are very marked, or, finally, where the patient, after having been warned of the danger of operative interference with the thyroid body, has refused to undergo the risk, the question of section of the sympathetic should be raised. The operation of ligature of the thyroid arteries which has been advised by many surgeons of the first class, such as Kocher and Rydigier, M. Poncet refused to discuss, as he said he had not enough experience of the operation to enable him to form any opinion as to its value.

Filtered Water for the Army.

M. de la Perriere read a paper before the Academy of Medicine upon the Rapid Purification of Water for Troops on Active Service. His method is to treat the water with a mixture of permanganate of potash, alum, and lime, and then filter it through wool impregnated with oxide of manganese. The whole process can be carried out by a filter which he has invented and which is no larger than the *bougie* of an ordinary filter; it sterilises and filters the water at the same time whatever be the degree of impurity.

Hygiene for Barbers.

At the request of the Hygienic Council for the Department of the Seine the Prefect of Police has just issued an order to all the haircutters of Paris containing instructions as to the measures to be taken for guarding against those diseases which are likely to be spread by the exercise of their trade. First of all, all metal instruments are to be plunged directly after use into a vessel of soapy water which has been boiling for at least ten minutes. All combs of tortoiseshell, ivory, celluloid, or buffalo-horn are to be replaced as far as possible by metal ones, so that they may the more easily be cleansed and disinfected: scissors, razors, clippers, and brushes are to be kept in a stove heated to 100° C. or in a closed receptacle in the lower part of which is a solution containing formaldehyde and sodium chloride in the proportion of 50 grammes of the former to 200 grammes of the latter. Before use, shaving-brushes must be dipped into boiling water, and instead of powder-puffs, blowers (*pulverisateurs à sec*) are to be used. Finally all hair-dressers must wash their hands before passing from one customer to another, and after anyone has had his hair cut, damp sand is to be sprinkled on the floor so that the hair may be swept up and burnt at the end of the day. The hair-dressers have protested against this order, which they declare to be quite inapplicable to their trade.

The Bacteriological Laboratory.

The total number of cases sent in to the bacteriological laboratory of the department of the Seine during the month of August for diagnosis was 147. Of these 94 were cases of doubtful sore throat, but in only 16 was the bacillus of Löffler discovered—that is to say that 17 per cent. of the cases examined during the month were considered diphtheritic. The figure is notably lower than that of July, 1897, when it was 19·6. In 1896 the number of deaths in Paris from diphtheria during August was 29, but in 1897 for the same month the number was only 12. Of the other 50 cases sent in for diagnosis 36 were cases of suspected tubercle, and in 15 of them the bacillus of Koch was found.

The Fight against Tuberculosis and other Diseases Affecting Meat as Food.

A certain number of departmental boards of works have sent in requests to the Government to take measures against the spread of tuberculosis. For instance, the board of works of the Côte d'Or says:—"Seeing the urgency of staying the spread of tuberculosis among live stock as much in the interest of the consumer as of the producer, this board considers that the authorities should seriously consider means towards the same, notably the employment of tuberculin to ascertain when beasts are affected; that a law should be passed making the use of tuberculin obligatory in the case of all beasts destined for the butcher or for the supply of milk; and that this law should at the same time order all such sanitary measures to be taken as are necessary for the complete extinction of this disease." The board of works of the Gironde

Digitized by Google

has adopted a resolution as follows: "That the law should define those diseases, whether contagious or not, which render meat unfit for food; that it should set out the penalties which may be exacted from those who prepare such meat with a view to its use as food; that it should order every commune to organise in all public or private slaughter-houses or knackers' yards a service for thorough surveillance which may seize and destroy all meat unfit for food; that in the draft Bill now submitted to Parliament as to abattoirs, &c., veterinary inspection of such establishments should be made obligatory; that such inspection should be a charge on the rates of the various communes, and that they should also be able to impose a *taxe de visite;* and, finally, that there should be an effective State control over the various local inspecting bodies, both administrative and technical, by means of special sanitary officers."

Malignant Pustule.

M. Le Roy des Barres has recently met with two cases of malignant pustule occurring in persons engaged in working with hair which had come partly from the Côtes du Nord, a district where no case of anthrax has been reported for several months, and partly from Buenos Ayres; four other cases were met with in patients who had been working among hides brought from Turkey and Kazan. The local use of the thermo cautery, injections containing 10 per cent. of iodine, together with the internal administration of oxygenated water and iodised water, were fortunately successful in saving the patients' lives. One of the patients who suffered from very marked general œdema of the whole of the upper part of the body, was in great danger for a long time, and it was necessary to inject pure tincture of iodine into the eyelid where the pustule had formed and where the bacteria were localised. In his communication to the Academy of Medicine M. Le Roy des Barres stated that in the course of some years he had observed seventy-two cases of malignant pustule, among which there were sixty-two recoveries. Fifty-seven of these patients were leather-dressers and fifteen were workers among hair. Anthrax is invariably conveyed by hides, skins, wool, and hair coming from abroad, and it is obvious that the importation of these products cannot be prohibited, and it is almost impossible to sterilise or disinfect them. At the same time cases of the disease are comparatively rare, treatment is said to be generally successful, and much may be done in the way of reducing the number of attacks by the adoption of hygienic precautions.

Sept. 20th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

"Pull Devil, Pull Baker."

WHILE a brilliant essayist has been amusing himself—if not his readers—on the subject, "Che Cosa Mangeranno I Posteri?" (What will our descendants eat?), and discussing the thesis of Berthelot that in the not remote future our "aliments will be manufactured with carbon taken from carbonic acid, with hydrogen and oxygen taken from water, with azote taken from the atmosphere," and so on, the dearness of bread has been agitating nearly every commune, from the Alps to Etna, bringing the proletariat and the poor into sharp collision with the bakers, throwing the bakers themselves "upon strike," and sending deputations from both interests—the consumers and producers—to magistrates, members of Parliament, and even the Prime Minister, the Marquess Di Rudini himself, without, however, as far as one can see, eliciting any hope of a way out of the imbroglio. Local circumstances intervened to modify the situation, which may roughly be described as this: the poor cannot afford to pay 40 centimes (4*d.*) for the "pagnotta" (loaf), and the bakers cannot afford to sell it at less unless the flour is supplied them at a figure below that at which the "dazio consumo" or octroi duty maintains it. What is occurring here occurs, *plus* "local colour," all throughout the kingdom. The Syndic invites the "Associazione dei Negozianti Fornai" (Association of Shop-keeping, as distinguished from "lavorants," journeyman bakers) to offer bread for sale at 40 centimes for the better quality and 38 or 35 centimes for the inferior. The "Associazione" replies, with flour at its present price, "Non possumus." A threat on the part of the Communal Administration to impose "prezzi coercitivi" (compulsory prices) on the bakers is met with a defiant "You had better try." At Venice the journeyman bakers go out on strike, and the "Municipio" (town council) orders two hundred "quintali" (hundredweight) of bread from Milan to keep the "Queen of the Adriatic" from starving; but the strikers have the grim satisfaction of seeing the said municipality constrained to sell it at 30 centimes the kilogramme, a significant commentary on the threat of "prezzi coercitivi." Meanwhile the lack of bread is bringing other aliments to the front, and the potato—in Italy a rather slighted esculent—is having its turn of popularity. Edibles of even humbler sustaining power are also invoked, with the result that "fungi" of more than suspected quality are multiplying the cases, already all too frequent, of "mushroom poisoning." Leaving the fiscal or economic aspects of the situation out of account, the crisis through which Italy is now passing is very grave. "Pazienza" has limits, even among her long-suffering population, and having seen herself deprived of "Circenses" (the gratuitous entertainments provided by the Bourbon) she may draw the line at deprivation of "Panem" as well! Malnutrition is one of the many curses of her labouring poor, infecting the life-blood of the rising generation, prolific of stunted stature, impaired muscular power, and generally of the diseased developments fraught with evil augury for her future. Vainly do her medical philanthropists, like Dr. Angelo Celli, Professor of Hygiene in our medical school, tax their ingenuity to invent a more nutritive dough than that employed by the baking interest. The crushing "dazio consumo" lays its paralysing finger on all such efforts, and forces men like Professor Celli and forty more of the same profession to court a seat in Parliament in order to cut at the root of the evil by fiscal amelioration and financial reform. Some twenty of these medical candidates were returned for as many constituencies at the general election in March last, and nearly all of them sit on the Extreme Left. And *quid mirum?* They are medical philanthropists first and political legislators afterwards; and their first thought is to raise the submerged masses from the slough of insanitation, with its attendant following of disease, crime, and anarchic conspiracy, and place them on the footing promised them when "Italy, one and independent," was substituted for "Italy, a geographical expression." A few figures will show what fearful abuses philanthropists like Dr. Celli and Dr. Colajanni are labouring to remove and agitating the public and Parliament to consider. In Naples alone malnutrition in 1873 caused 131 deaths "con vizi di conformazione congeniti" (congenitally abnormal conformation); and in 1896 the number had risen to 240. In the same city, in 1873, there were 1216 deaths from tuberculosis in its various forms, and in 1896 they rose to 1812. Increase of population does not explain this evil increment, which, as Dr. Colajanni remarks, is "graduale, costante." The Di Rudini Government will soon have to face a reassembled Parliament; and one of its first duties will be to consider the ill-nourished, badly housed, hygienically neglected poor—to leave the "Dark Continent" to take care of itself and to brighten that still darker region around it—the true "Italia Irredenta"—which seethes, suffers, and succumbs.

Sept. 19th.

THE PLAGUE AT POONA AND KIRKEE.—The plague still continues to prevail at Poona, Lanowli, and Kirkee. The bazaar at Kirkee is closed. According to the *Times of India* of Sept. 3rd, twenty-eight cases and twenty-three deaths from plague were reported in one of the latest returns. M. Haffkine is carrying on inoculations at Kirkee, and fresh cases, many of them fatal, were occurring in the cantonment. Surgeon-Major J. P. Barry's trenchant report on Poona city has, as it certainly deserves to do, attracted a good deal of attention. It discloses a dreadful state of things, and although the municipality in their reply traverse many of the allegations their answer cannot be regarded as very successful. Moreover, the report of the municipality was only signed by seven of its members, while two recorded their general approval of Surgeon-Major Barry's report. Lord Ripon's schemes for the introduction of municipal government into India have proved a failure, and, as regards the progress of sanitation in that country, their effect has been anything but good.

Obituary.

ARTHUR BRISLEY RYE, F.R.C.S. ENG., L.S.A.

ANOTHER old practitioner of a past generation has joined the great majority; the subject of this notice passed away painlessly at his residence, Westbury, in the pretty valley of Caterham, on the evening of Sept. 1st, at the advanced age of eighty-five years, and in the full possession of all his faculties. Mr. Rye came of a medical family, and was born in Rochester in 1812, where his father practised as a surgeon. Mr. Arthur Rye qualified in 1836, when he obtained the L.S.A. Lond., and in the following year became M.R.C.S. Eng., and was made a Fellow of the College in 1852. He commenced practice as an assistant to Mr. Harrison, of Greenwich, with whom he remained some time, and then went into private practice at Banbury, in Oxfordshire, where he practised successfully for over thirty years, and won the esteem and confidence of his brother practitioners. Mr. Rye was an enthusiast in his profession, and although he had retired for many years he was never happier than when he could assist a medical friend by giving him a holiday and taking charge of his practice. Mr. Rye had one of those happy, genial dispositions which are always cheerful and humorous, and for his skill and kindness he was much esteemed by his patients. For some years after his retirement Mr. Rye resided at Leckhampton and took great interest in the building and opening of the Delancey Fever Hospital of which he acted as the hon. superintendent for some time. Those who knew him loved him; not a few were the happier for his life; and many a general practitioner will mourn his death and sympathise deeply with Mrs. Rye and family in their loss. Mr. Rye was twice married and leaves one son and one daughter.

ADAM FLETCHER, M.D. EDIN., M.R.C.S. ENG., J.P., &c.

BURY has to mourn the loss of her oldest medical practitioner in the person of Dr. Adam Fletcher, who passed away at his residence, Belgrave-place, Manchester-road, on Aug. 28th. Dr. Fletcher had been in practice in Bury for nearly fifty years. He commenced his medical education under the late Dr. Thomas Wardleworth, and proceeded to Edinburgh University. In all local matters he took a warm interest, was one of the consulting medical officers to the Bury Dispensary Hospital, a churchwarden of the parish church, President of the Bury Ragged Schools, and a member of the Borough and County Benches of Magistrates. For some twenty years also he was a member of the board of management of the Bury Savings Bank. The funeral took place on Wednesday, Sept. 1st, and was very largely attended by relatives and friends, besides representatives of the various public bodies with which the deceased had been connected. At the first meeting of the Borough and County Benches of Magistrates the chairman made sympathetic references to the loss sustained by the death of a colleague for whom they had all such deep respect and affection.

R. J. STEPHENS, M.R.C.S. ENG., L.S.A.

ANOTHER death must be added to the tale of those caused by bicycle accidents, by which a promising career has been sacrificed. On Sept. 11th Mr. R. J. Stephens, of Whittingham, Lancashire, was riding down a gentle slope with his feet up on the rest when his machine was suddenly seen to swerve, and Mr. Stephens fell off, striking his head with great force against the road. He was picked up by his companions, also medical men, and conveyed in an ambulance to Preston Infirmary, where he died the same night. Death was due to a large hæmorrhagic effusion in the brain. The deceased never recovered consciousness after he fell. Richard John Stephens was the son of the late Richard John Stephens, of Kent, and has a brother, also a medical man, in practice at Brighton, as well as a stepbrother, A. C. Dickson, now studying medicine at Cambridge. He was educated at King's College School and passed the matriculation examination at London University; he was also an Associate of King's College. He received his medical education at King's College Hospital, where he held the appointments of assistant demonstrator of physiology and resident accoucheur. He had also been resident medical officer to St. Luke's Hospital, house surgeon to the Blackburn and East Lancashire Infirmary, and assistant medical officer to the Wilts County Asylum, while at the time of his death he was assistant medical officer to the County Asylum, Whittingham. The body was moved on Sept. 15th from the Preston Infirmary to the residence of the deceased's mother, at Blackheath, and interred the following day in the grave in which rests his father's body. During his residence in Lancashire Mr. Stephens made a very large number of friends, by whom their loss will be most keenly felt. His honourable character, and his kindness, sympathy, and consideration for others, which never allowed him to turn a deaf ear to a friend in trouble, endeared him to all who knew him. Mr. Stephens was only thirty-four years of age at the time of his death.

MARK BATT TANNER, M.D. R.U.I. AND ST. AND., M.R.C.S. ENG., L.R.C.P. LOND. AND EDIN.

DR. TANNER, whose death in London on the 14th inst. was announced in our columns last week, at one time practised in Brighton and Hove, where his services were highly esteemed by an extensive circle of patients. He was, however, best known to the public as a prominent Freemason and an effective platform-speaker. Dr. Tanner was formerly one of the principal masonic officers in the province of Sussex, being Past M.W. Sovereign and Recorder of the Eureka Chapter, a member of the 31st degree, and a Past Master of the Yarborough Lodge. Although it is now about fifteen years since he left Brighton, he is still remembered in political circles there on account of the valuable support which he gave to Mr. James Ashbury, at one time the member for the borough. Dr. Tanner was sixty-five years of age at the time of his death. He graduated as M.D. in 1861, both at the Royal University of Ireland and at St. Andrews University. The funeral took place in Hove Cemetery, on Sept. 18th.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men have been announced:—Dr. Welcker, who was for a great number of years Professor of Anatomy in the University of Halle, died last month at Winterstein. He was born in 1822 in Giessen, and studied in that university and in Bonn, taking his degree in 1851. It was not long before he began to give evidence of his ability by writing important papers on physical and physiological subjects, many of which were connected with optics. Subsequently he made some valuable researches on the blood, the anatomy of the ventricles of the brain, and the development of the skeleton. He did not entirely confine himself to medical science, for he found time to publish a work on German poetical dialects. His first chair was in Giessen, where he taught anatomy both as *privat-docent* and then as professor. In 1859 he accepted an invitation to teach anatomy in Halle, from which chair he only retired in 1894. In 1876 he was appointed to succeed Professor Volckmann as Director of the Halle Anatomical Institute.—Dr. R. Berlin, Professor of Ophthalmology in the University of Rostock.—Dr. Surmay, Corresponding Member of the Paris Academy of Medicine.

MILK ADULTERATION.—At the Bristol Police-court, on Sept. 9th, a tradesman was summoned for adulteration of milk. The case had been adjourned in order that a third sample of the milk might be submitted to Somerset House for analysis. The city analyst certified that one sample contained not less than 7 per cent. of added water and another not less than 5 per cent. The analysis from Somerset House showed that the sample had not less than 4 per cent. of added water. Another analyst stated that he had examined two samples submitted by the defendant, and found they contained 5 and 6 per cent. of added water; he had analysed milk taken direct from the cow in his presence and found that it contained 5 per cent. of "added" water according to the present standard. The magistrates said they thought the justice of the case would be met by the payment of costs, and they made an order accordingly.

THE BRITISH MEDICAL ASSOCIATION.

MEETING AT MONTREAL.

THE SECTIONS.

MEDICINE.

THURSDAY, SEPT. 2ND.

The Dietetic Treatment of Diabetes.

DR. ROBERT SAUNDBY (Birmingham) opened a discussion on this subject. When the diagnosis of diabetes mellitus has been established, he said, sometimes when only the presence of sugar in the urine has been detected, it is the very general practice to place the patient upon a so-called "diabetic diet"—that is to say, he is furnished with a list of permitted and forbidden articles of food and drink arranged upon the principle that all carbohydrates are injurious, and he is told that he must keep to this diet until the sugar has disappeared from his urine. But carbohydrate food is not the only source of sugar. In severe diabetes glycosuria continues, although much reduced in amount, when the patient is placed on a flesh diet, and this is explained by the discovery that a carbohydrate molecule is formed in the process of converting albumin into urea, in the proportion of forty-five parts per cent. This fact, duly appreciated, must convince every one of the futility of persisting in withholding carbohydrates in the hope of removing the glycosuria. If it is conceded that the disputed data of physiologists do not afford a sound basis for our treatment of diabetes, but that we must look to clinical results before we say that a means is good or bad, then the old routine method is doomed. Instead of ordering a stereotyped diet in every case we must try experimentally in each individual how much carbohydrate, or, rather, what combination of proteid, fat, and carbohydrate gives the best result. This was the method which the speaker would advocate, and it had been adopted solely upon the basis of clinical experience. The method, he said, does not involve a great sacrifice of time on the part of the medical man; in fact, all the most important observations can be made and a register kept by the patient himself. The only thing he cannot do is the analysis of the urine. The patient should once weekly get weighed, and collect and measure the whole of his urine for twenty-four hours; a specimen of the urine should be sent to the medical man, who should determine the total amount of sugar. Of these observations, the body weight is the most important, for if it continues to be stationary or tending upward we have the best proof that the diet is properly regulated, even though the sugar shows a moderate increase. In order to determine the diet most suitable to each patient we must proceed experimentally, and this is better done by gradually increasing the amounts of saccharine and starchy food. Many patients suffer from polyuria and great thirst, and these symptoms can best be checked by strict diet for a limited time, combined, if necessary, with the administration of a grain or two of extract of opium every night. Further, the result of strict diet affords valuable information for prognosis, as it is only in the milder cases that the sugar disappears under its influence. The patient should, if possible, make one meal—for example, breakfast—of fat bacon or eggs and bacon, with which he may eat cabbage and starchless, not gluten, bread or biscuits. He is, of course, allowed other green vegetables, any animal food, tea or coffee with cream, and, if he desires it, two or three ounces of sugar-free alcohol, with mineral water. When after a week of this diet the sugar is found to have disappeared entirely, or almost entirely, six ounces of baked potatoes and one and a half pints of milk, containing between them the equivalent of about 1100 grains of sugar, may be added. If this causes no glycosuria four and a half ounces of dry toast, of which about 800 grains are starch, may be given, as also a bottle of light wine containing very little sugar, such as ordinary Bordeaux or Moselle, or in some cases a pint of bitter Burton ale. If such a diet causes no return of symptoms the medical man may be satisfied and the patient is generally contented, and if sugar continues to be absent the quantity of toast or bread may be gradually increased to double the amount. Such cases are, however, exceptional. As a rule the sugar, though diminished, persists. In such a case we may give first the milk and then the potatoes, and if there is no return of distressing symptoms we should not retrace our steps because there is some moderate increase of sugar, but watch the body weight. If that shows no loss we may keep the patient on this diet for many weeks before venturing to make a trial of ordinary bread, and often the patient has to be content to do altogether without it. Dr. Saundby preferred to increase the potatoes, for he was of the belief that the starch of cereals is for some reason more productive of glycosuria than that of potatoes.

In the discussion which followed DR. COUPLAND said that each individual case should be dieted as the condition of the patient indicated, but that diet would often not have the desired effect.—DR. SHINGLETON SMITH (Bristol) urged that greater indulgence might be permitted in the use of carbohydrates.—DR. TYSON (Philadelphia) divided cases of diabetes into mild and severe, and considered that in mild cases the sugar could be eliminated by diet alone, while in the severe cases no diet seemed to be of use. Pure proteid diet he believed to be harmful because of its transformation into toxic substances, while, when the sugar could be kept under 2 per cent. by a limited use of carbohydrates it was advisable to do so, estimating the amount excreted every month.—Professor JACOBI (New York) and DR. STEPHEN MACKENZIE, the President of the Section, and others took part in the discussion, the general conclusion being that in the diet of the diabetic patient too strict a routine had been hitherto followed.

FRIDAY, SEPT. 3RD.

Cholelithiasis.

A discussion was opened by DR. WILLIAM HUNTER (London) on Cholelithiasis, its Causation, Symptomatology, Diagnosis, and Treatment. He said that the disease in question was eminently suitable for discussion, inasmuch as it was of frequent occurrence, obscure in its course, entailed much suffering and often death, was variable in its symptoms, and the diagnosis was frequently difficult and doubtful. He would deal especially with the chemical problems involved, and with the causation of the disease. Until lately there had been little advance upon the subject for 150 years, when Dr. Coe summarised the state of existing knowledge, attributing the disease chiefly to stagnation of bile, the result in many cases of tight-lacing or pregnancy. The disease was five times more frequent in women than in men. In the speaker's opinion it was a local disease of the bile-passages and gall-bladder, rather than a general constitutional disease. The pressure under which the secretion of bile took place was very low, hence its course was very dependent on extraneous conditions, such as the movements of the diaphragm. The flow of the bile was also dependent upon the walls of the hepatic duct and of the gall-bladder. Gall-stones consisted chiefly of cholesterin and of bile pigments associated with lime salts. Cholesterin was widely distributed throughout the tissues. It was found in the nerves, ovaries, blood, testis, yelk of egg, &c. There was no evidence that cholesterin was secreted by the hepatic cells; rather was it the product of degenerated cells. It was especially abundant in the secretions of mucous membranes. It was more abundant in the sputum of bronchitis and phthisis and in pus than it was in bile. The inflamed mucous membranes of the bile passages were the probable seat of the formation of the cholesterin in gall-stones. Bilirubin and calcium did not combine in the bile, but if egg albumen be added they were thrown down in combination. Hence free albumin was probably present in the bile passages as the result of catarrh. The conditions favouring the formation of gall-stones were essentially local, the result of catarrh. The causes of this catarrh were stagnation of bile, the result of sluggish habits, pregnancy, tight-lacing, &c. Stagnation of bile alone was not sufficient to cause cholelithiasis, inasmuch as it was not excited by the mere stagnation of bile, normal bile being quite aseptic; but stagnation of bile gave rise to infective processes, and the presence of the bacillus coli communis and the bacillus typhosus. These organisms were derived from the intestine. A second cause of gall-stones was inflammatory catarrh of the inter-hepatic bile ducts set up by irritant products in the bile the result of dietetic errors. Treatment should be directed to flushing the bile passages with water as much as possible. Carlsbad and Vichy salts were very useful, and salicylate of soda was known to

Digitized by Google

promote the flow of bile. No drug acted as a solvent of gall-stones when once formed.

Dr. GRAHAM (Toronto) continued the discussion. Biliary colic occurred in less than one-half of the cases of gall-stones. The seat of the pain was usually in the region of the gall-bladder, but might be in the shoulder or in the right inguinal region. The severity of the pain was not due so much to the size as to the shape of the gall-stone. Death had been known to occur during an attack of biliary colic. Biliary colic without jaundice might give rise to great difficulties in diagnosis. Elevation of temperature occurred and rigors, which were toxic in origin and did not indicate suppuration. Jaundice was absent in one-half of the cases of biliary colic. It might follow the attack of colic at a long interval. Bile pigment might be found in the urine, and its presence there might assist the diagnosis. Distension of the gall-bladder might take place from atony of its walls, when there was little or no obstruction. Calculi were often the cause of carcinoma. The duodenal end of the common duct was a frequent seat of carcinoma. Cholelithiasis was often associated with diabetes. Gall-stones might be a cause of intestinal obstruction.

Professor OSLER (Baltimore) thought that the association of typhoid fever and gall-stones was much more frequent than was usually supposed. There were four varieties of fever associated with gall-stones: 1. The fever associated with the chill. 2. The fever associated with cholecystitis. 3. "Hepatic intermittent fever." In these cases attacks resembling miliary intermittent fever occurred through weeks, months, or years. They were usually followed by slight jaundice. There was no fever in the intervals, the patient felt well, and the jaundice diminished. 4. Fever associated with suppurative processes.

Dr. HANDFORD (Nottingham) had not seen any clinical evidence to warrant the theory of a relation between typhoid fever and gall-stones. Gall-stones were not so very rare in the young.

Dr. MULLIN (Hamilton, Ontario) did not believe in the association of gall-stones and typhoid fever.

Dr. BAUMGARTEN (St. Louis) thought that in cases of associated gall-stones and carcinoma the latter was primary.

Dr. MACKINNON (Guelph) had lately seen two cases of gall-stones following typhoid fever.

Dr. PASTEUR (London) gave the history of a case illustrating the occasionally extreme difficulty of diagnosis in these cases.

Dr. ROGER (Denver) and Dr. ACHESON (Galt, Ontario) continued the discussion.

The PRESIDENT of the section summed up. He thought that now attention had been drawn to the subject the association of typhoid fever and gall-stones would be found more frequent than had been supposed. He agreed with Dr. Osler that he who knew the subject only from the medical side knew but half. He was inclined to think that obstruction was always at the bottom of biliary colic and that spasm would not account for it.

Dr. HUNTER having replied, the discussion came to a conclusion.

The proceedings terminated with a vote of thanks to the President of the section.

SURGERY.

THURSDAY, SEPT. 2ND.

The Operative Treatment of High Cancer of the Rectum.

A discussion took place upon this subject, which was opened by Dr. JAMES BELL (Montreal). After remarking on the frequency of the disease in this situation, and quoting Mr. Bland Sutton as authority for the statement that of every hundred cases of carcinoma of the intestine seventy-five occurred in the rectum he referred to the difficulty of early diagnosis owing to the indefinite nature of the early symptoms. Even when loss of blood occurred with irregularity of the bowels and flatulence the disease was often not suspected. It was only when symptoms of auto-intoxication, with sanious or mucous discharges from the bowel, occurred, that an examination of the rectum revealed the true condition of affairs. Operable cases were: (1) those in which there is a chance of removing the whole mass with permanent cure; and (2) those in which, though the mass is removable, the probability of recurrence is strong. In still another class, in which there is no hope of removal, inguinal colotomy should be done. The first grave symptom might be a general peritonitis due to rupture and escape of contents into the peritoneal cavity. After discussing various methods he recommended Kraske's operation by the sacral route. He preferred to make a preliminary inguinal colotomy to define the upper limit of the growth and to estimate the amount of glandular involvement, while free evacuation and cleansing of the bowel were thus made possible, and, should a permanent artificial opening become necessary, the inguinal opening was much better than the sacral one. The essentials to successful resection were a clean field of operation, free descent of the proximal end of the bowel without tension, and careful suturing. He thought that there was quite an unnecessary dread of bringing down the upper segment of the bowel for fear of sloughing. The danger was rather of pulling and stretching and otherwise depressing the blood supply. He thought it was unavoidable to open the peritoneum in high operations on the rectum, but said that this was not to be feared if the opening was afterwards closed with sutures and the site of the wound was properly dressed and drained. The operation was not without considerable danger, but the average rate of mortality after the operation was not greater than 20 per cent., and 10 or 12 per cent. of the patients remained well and without recurrence for four years.

Professor C. B. BALL, Regius Professor of Surgery in the University of Dublin, gave a lantern demonstration illustrating Trans-sacral Resection of the Rectum. He said that he did not perform an osteoplastic operation, but removed the lower segment of the sacrum entirely. He believed that the perineal route should be discarded, except, of course, in those cases in which the anus was involved. The best recoveries in these cases were those in which the tumours were freely moveable. As preliminary to the operation he usually gave purgatives for several days, together with rectal enemata, to insure thorough cleansing of the bowel. Then he used a 2 per cent. solution of creolin to wash out the bowel, and gave opium to prevent peristalsis. One danger that had been mentioned was that of sloughing. This could be avoided largely by care in manipulation. The parts should not be too tense and should not be pressed upon. He reported seventeen cases with sixteen recoveries from the preliminary operation. He thought that we should operate for present relief, even when the cancer was high up and the glands were involved. He preferred this operation to colotomy.

Dr. W. W. KEEN (Philadelphia) said that there was no doubt that Kraske's operation was of great importance and offered relief to many sufferers. Even when the glands were considerably involved he had found that patients improved very much. He did not think the osteoplastic method was at all necessary. It was his custom to remove the coccyx and the adjoining portion of the sacrum, but he differed from Professor Ball and agreed with Dr. Bell as to the advisability of doing a preliminary inguinal colotomy, whether temporary or permanent. But the two operations should never be done at one sitting, it being better to wait two or three weeks for the subsequent operation. Kraske's view was that a preliminary colotomy was to be done only in case the obstruction was so complete that this cleansing could not be effected without it, but Dr. Keen thought that the operation was necessary to unload and cleanse the bowel. He reported twenty-five cases. Of these, fifteen were sacral operations, and there were twelve recoveries, four of which had passed the four-year limit, which he considered to mark the chances of recurrence.

Dr. ASHHURST (Philadelphia) said he was never very enthusiastic about operation for the removal of cancer of the rectum, although his views had become somewhat modified since visiting Montreal. He thought that if the disease had gone on to obstruction it was better to make an artificial anus. He was in favour of doing the preliminary colotomy as a safeguard, for in some cases if resection was done without this preliminary step there occurred a low form of peritonitis, accompanied by vomiting, so that it was difficult to nourish the patient; whereas if there was an opening in the colon this could be used for the introduction of food and saline or other injections without interfering with the rectum itself. He mentioned a procedure of a palliative character which he had found very useful; that was a small longitudinal section of the rectum through the mass of disease in the median line posteriorly.

Gunshot Wound of the Spinal Cord.

Dr. GEORGE A. PETERS (Toronto) followed with a paper

Digitized by Google

on this subject. He stated that the causes of death in such cases were shock, hæmorrhage, and septic processes, while the factor which most largely determined the rate of mortality was the proximity of the cord lesion to the brain. Cases of this nature in civil practice were very infrequent. Although there had been cases in which, after complete transverse lesion of the cord at various levels, the individuals had survived for periods varying from one to twenty-six years, yet it might be stated as a rule to which the exceptions were few that patients with such lesions died within a year of the injury. The determining causes of death were inflammation of the bladder and its sequelæ, bed-sores and other trophic lesions, pyæmia, amyloid disease, and exhaustion. He recommended medium cystotomy as a routine practice in cases of this injury in male subjects, so as to imitate the short and straight urethra of the female, as the latter seemed to suffer less from bladder symptoms. Dr. Peters then referred to the difference between the deep or tendon reflexes which were permanently lost in complete transverse lesions of the cord, and the superficial or skin reflexes which, as in a case narrated by him, might not only return, but might even become exaggerated. He believed that in the case of the skin reflexes the reflex arc remained intact and the exaggeration was accounted for by the overflow of sensation into the motor regions in the cord, which were relieved of the natural inhibitory influence of the higher centres by the lesion; while in the case of the tendon reflex an influence was normally transmitted to the muscles to maintain their tone which was also interrupted by the lesion—hence the permanent loss.

FRIDAY, SEPT. 3RD.

A Case of Abdominal Tumour.

Dr. F. J. SHEPHERD (Montreal) opened the proceedings of the day by reading a paper on a Case of Abdominal Tumour, in which nearly 8 ft. of small intestine had been resected. He said that these cases were not uncommon, but the present case ranked second in the amount of intestine removed, the first being that of a Roman physician, who had removed about 11 ft. of intestine. The present case was that of a young man with an abdominal tumour filling up the whole cavity of the abdomen and adherent to about 3 ft. of the small intestine. A very long, vertical incision was made in the median line and the tumour was then found to be of the mesentery. The tumour, with the bowel to which it was attached, was then removed, and from the destruction of mesenteric vessels it was found necessary to make a still larger resection of small intestine. In all 8 ft. were removed, this bowel consisting of ileum. During the operation, which lasted one and a half hours, the patient became very weak, necessitating an intravenous saline injection. Nutritive enemata were given after operation for some days. On the sixth day the patient had a stool, and after this there was some tendency to diarrhœa. One month after operation the patient was well enough to go out driving, and five weeks after operation left the hospital cured, and has gained very much in weight since. Dr. Shepherd then read the results of resections in dogs by Dr. Senn. The tumour was examined microscopically by Dr. Wyatt Johnston and proved to be a fibro-myxoma. The tumour and the adherent bowel were exhibited, and the members had the pleasure of seeing the living patient, who was in apparently excellent health.

The Diagnosis and Treatment of Penetrating Wounds of the Abdominal Cavity.

Dr. TOBIAS NUNEZ (Mexico) then read a paper on this subject. Stress was laid by the speaker on the great difficulty in diagnosis in deep wounds. He touched upon the method of diagnosis by the use of hydrogen gas. Wounds caused by firearms were alluded to. The diagnosis could only be made by one of the complications—viz., hæmorrhage and septic peritonitis—when operative measures failed very frequently because of rapid progress of these complications. In treatment no food whatever was to be taken by the mouth; pounded ice might be taken from time to time. Opium, in his opinion, was the best drug to be used in these cases. Laparotomy he did not perform until diagnosis was sure.

The Surgery of the Gall-bladder and Bile-ducts.

Dr. ALEXANDER FERGUSON (Chicago) then read a paper embodying his personal observations on this subject. He based his remarks on the observation of 46 cases. The therapeutist, he said, was at sea, and the surgeon alone could deal with these cases. The more chronic the affection the more difficult was the means of affording relief, hence the advantage of early operative interference. He reported 3 cases of flexion of the gall-bladder relieved by operation and 4 cases of dropsy of the gall-bladder, one of which reached as far down as the brim of the pelvis, and one of which was operated upon under cocaine anæsthesia. It was interesting to note that it was only necessary to cocainise the skin and peritoneum. Cholecystotomy was performed in 37 cases with but 2 deaths. The perpendicular incision about the tenth rib was preferred. The bladder was opened, and if bile was present it was washed out, the bladder first being stitched to the peritoneal wall and upper angle of the wound. Patency of the common duct was proved by passing a small probe, and if this was impossible by the forced injection of sterile water. Dr. Ferguson had opened the common duct five times.

Stone in the Ureter and its Treatment.

Mr. JORDAN LLOYD (Birmingham) read a paper on this subject. Many operations, he said, were performed for stone in the kidney with failure to find the stone, the patient presenting the symptoms of renal calculus. These cases he thought were probably due to the stone being located in the ureter. He laid stress on the absence in renal calculus of severe tenderness on pressure in the loin over the kidney. The symptoms of ureteral calculus were like those of renal calculus, but there was less local pain. Situations of the stone were: between the pelvic brim and the bladder, at or near the wall of the bladder, and between the pelvic brim and pelvis of the kidney. The results of ureteral occlusion were: (1) atrophy of the kidney; (2) dilatation of the ureter; and (3) pyelitis. These inflammatory conditions generally preceded the passing of an instrument. The stone might be present in the ureter for many years. The hæmaturia was greater in ureteral than in renal calculus. The symptoms of water-logging of the kidney, which Mr. Lloyd grouped as urine toxæmia, were accompanied by extreme distress, little pyrexia, and always by abdominal distension. These toxins weakened the heart and increased the rapidity of the pulse. The distension of the bowels was probably due to some paretic effect due to the toxins. Stress was laid on digital rectal examination, which could detect a stone even high up in the ureter. Treatment depended on its position. If near the bladder the best method was by suprapubic cystotomy; if higher by abdominal section, pushing up the peritoneum and opening the ureter posteriorly and extra-peritoneally. In this operation the ureter was not sutured, as no urine was found to come through the wound. The operation was similar to that for ligature of the common iliac artery. If the stone was situated higher the lumbar operation could be done. A drainage-tube was used in the last two. Two specimens of ureteral calculi were exhibited which Mr. Lloyd had removed.

Dr. KEEN (Philadelphia) cited a case where he had mistaken a case of ureteral calculus for appendicitis. The cause of trouble was not found at the operation, but only some months later, when the patient was operated on and a calculus removed from the bladder. His views coincided with those of Mr. Lloyd. He recommended washing out the bladder with Bigelow's catheter after every attack of renal colic. Dr. Keen also emphasised the value of thorough digital rectal examination.

Dr. SHEPHERD asked why Mr. Lloyd had used the drainage tube if no urine escaped through the wound and what was the reason of there being no escape.

The President of the section, Mr. CHRISTOPHER HEATH, cited a case which was mistaken for an ovarian disease. It was better, he thought, to open the bladder and proceed from this in the operation.

Mr. LLOYD, in reply to Dr. Shepherd's question, said that the reason for the non-escape of urine was probably due to the blood, &c., acting as a seal to the wound, and the passage through the ureter being free for urine to escape into the bladder. The tube, he said, was only placed about an inch from the ureteral opening and was used in case there should be any escape of urine.

Papers were also read in this section by Dr. LAPTHORN SMITH (Montreal) on Appendicitis, and Dr. A. B. ATHERTON (Frederickton) on a Case of Intestinal Obstruction.

The proceedings terminated with a vote of thanks to the President of the section.

PUBLIC MEDICINE.

THURSDAY, SEPT. 2ND.

Small-pox in Montreal.

The business of the section commenced by a warning of the President, Dr. E. P. LACHAPELLE, against attaching unnecessary importance to the newspaper reports of an outbreak of small-pox in the city. In Montreal since the outbreak on July 2nd there had been 13 cases. 5 of which had died, leaving 8 patients sick. They were all in the small-pox hospital, and there was not a single case known in the city outside the hospital. In Westmount, a town adjacent to Montreal, there were only 5 cases, all in the same family except one, an official, who caught the disease while having the house disinfected. There were now in Westmount 4 patients and 8 in Montreal, making 12 in all. There was 1 other case in St. Cunegonde, another suburb of Montreal.

The Utility of Quarantine.

An important discussion on this subject was opened by Dr. F. MONTIZAMBERT (Quebec), general superintendent of the Canadian Quarantine Service. He reviewed the Canadian system, and pointed out that owing to the different conditions prevailing it differed from the British system in several respects. Canada, for example, accepted fully the conclusions of the Dresden Sanitary Convention without the reservation made by Great Britain that healthy persons landing from infected ships should not be detained. In Canada, also, disinfection of the mails was occasionally considered advisable, especially when arriving from China.

Dr. WYMAN, supervising surgeon-general of the United States Quarantine Service, described the system in force in the United States.

Dr. J. A. DUNCAN, secretary of the Provincial Board of Health of British Columbia, read a paper on the Value of Quarantine on the Pacific Coast, in which he recommended that Chinese emigrants and their baggage should be disinfected and kept in quarantine one fortnight before coming on board any ship at any Chinese port.

Dr. MONCKTON COPEMAN, of the Local Government Board, London, described the survey of the English coast made by the Board some three or four years ago when quarantine was abandoned in England.

On the Duration of the Period of Infectiousness in Scarlet Fever.

Dr. JAMES T. NEECH (Atherton), physician to the Leigh Joint Fever Hospital, then read a paper upon the Infectiousness of Scarlet Fever. "The period," he said, "when a convalescent from scarlet fever ceases to be infective and becomes safe for discharge must at times be a source of anxiety to every physician who has charge of a fever hospital, and it appears to me that this uncertainty is likely to continue more or less until the specific microbe of the disease has been definitely isolated, its life-history studied, and the extreme limit of its retention within the human body experimentally proved; not till then and not till we have at our disposal reliable methods for detecting the microbe shall we be enabled to pronounce with certainty that a given patient is free from infection and incapable of conveying the disease. Until we arrive at exact methods we must be guided in dismissing patients from hospital by the result of close observation, accurate records, and carefully prepared statistics in connexion with the cases while in hospital, and the relation which their discharge therefrom bears to the occurrence of fresh cases in the district to which they belong. By this means it would be possible in time, I think, to acquire fairly accurate information with regard to the probable period during which a case of scarlet fever continues to be infectious. That the period of infectiousness varies in different cases is true, and doubtless the severer the fever the longer is the case likely to continue infectious. Hitherto the generally recognised period during which isolation should be maintained in mild and ordinary cases is six weeks provided desquamation is complete. In my opinion that period is too short even in the milder cases, and although I admit that the desquamating cuticle is infectious I am not certain that the completion of desquamation is a safe and reliable guide as to when a given patient ceases to be infective even in cases where no complication arises. That a purulent discharge from the nose, ear, or running sore, the usual sequelæ and complications which necessitate a prolonged period of isolation, is infectious has been proved beyond a doubt. But what is the source of the specific poison in these discharges? Do these discharging surfaces afford conditions in which the specific microbe can increase and multiply? The discharge itself comes from the blood-vessels, and if the blood has been rendered immune to the disease, are not these discharges in consequence inimical to the growth of the microbe? In my opinion the source of the specific poison is not the mucous membrane of the nose, or ear, or the surface of the sore, but the blood-stream, that the mere existence of such discharging surfaces are not in themselves capable of prolonging the period of infectiousness, and that they only serve as exits by means of which a portion of the virus finds its way out of the circulation and the body. It has not yet been shown that the cessation of the period of infectiousness and the healing of a discharging surface are coincident, and I do not think that such is always the case. Sometimes possibly the healing precedes, while at others I feel sure that infection ceases before healing takes place. A discharge sometimes continues through a very protracted period, but it is obvious that infective material cannot be retained within the body indefinitely, and although the period of infectivity may vary in different cases, is there not a time limit to the retention of the virus in the body beyond which no complication whatever can prolong the period of infectiousness? In cases of infectious disease where the fluids of the body are more or less laden with specific poison a certain time must elapse, under the most favourable circumstances, before the poison can be completely eliminated, and in scarlet fever it appears that conditions exist in certain cases which considerably prolong the period of complete elimination. In this respect scarlet fever seems to differ somewhat from other fevers, consequently the idea suggested itself that a storing up of infective material takes place somewhere in the body, and this, perhaps, in the condition of spores. I have noticed in scarlet fever that not only the glands of the neck, but also the lymphatic glands in the axilla, groin, and other parts become enlarged during the earlier stages of the disease, and that this enlargement is more marked and general in the severer forms of the disease. Therefore I incline to the opinion that the poison accumulates in these glands, causing irritation and enlargement. As the irritation ceases and the enlargement becomes absorbed the virus passes again into the blood-stream, and is eliminated during convalescence by the different emunctory organs. In typhoid fever great care is bestowed upon the disinfection of the discharges from the bowels and kidneys, and especially the former, but in scarlet fever little attention is usually paid to these excretions. When the fluids of the body contain a specific poison, is it not capable of being discharged therefrom by every organ the function of which it is to separate effete materials from the blood-stream? I think the desquamating cuticle, especially in the later stages, owes its infectiousness very much to the excretion of the glands of the skin. With a view of obtaining information as to the usual length of hospital isolation in this disease I issued a circular to a number of fever hospitals situated in different parts of England asking for the minimum, maximum, and average period of isolation that obtained in each place during the two previous years, and also the number of return cases which occurred within seven days of the discharge from hospital. From the replies received I find the minimum period varied between four and eight weeks, while the maximum in some cases extended to six months. The average period, the most useful for the purpose of comparison, varied between thirty-nine and sixty-five days. In many hospitals information regarding the number of return cases did not appear to be available, but I have been enabled to secure pretty accurate records of some 15,000 cases, and find that where the average period of isolation was forty-nine days and under the return cases averaged 1·86 per cent., where the average period of isolation varied between fifty and fifty-six days the average percentage of return cases was 1·12, and where isolation extended to between fifty-seven and sixty-five days the average percentage was 1·0. Although I would not like to lay too much stress upon these figures, yet they seem to point to the conclusion that the average period of retention in hospital bears a relation to the number of return cases of the disease. The question of return cases of scarlet fever is an important and very difficult one. Of course, a patient might become infected in the ordinary way, or might contract the disease from some source with which we are ill acquainted, and in each case this might be coincident with the return from hospital. The stowing

Digitized by Google

away of infected articles belonging to a patient has been shown to be a cause of return cases, but with improved apparatus and more perfect and thorough methods of disinfection this probably does not play so important a part in the matter as formerly. Allowing that a certain number of return cases contract the disease from other sources, yet there is little doubt but that discharged patients are the direct vehicles of infection in a certain percentage of cases. Several eminent authorities are of opinion that patients through breathing the actively infected air of a hospital during convalescence store up infective material in the cavities of the nose and lungs, and by that means convey the poison outside the institution. This may possibly occur; but were it the chief cause, would not the number of return cases be even greater than it is? Moreover, it appears to me in that case the percentage would not be affected by prolonged hospital isolation in the way the figures quoted seem to show. The lymphatic glands I think store up infective material. This has been previously referred to, and should any enlargement be found when a patient is examined for discharge it is now my practice to prolong the stay in hospital in consequence thereof. Systematic disinfection of the nasal cavities before discharge has been advocated, which no doubt is a useful and necessary procedure, also a convalescent ward in which patients may be prepared for a week before dismissal. I think there should be two such wards in connexion with large hospitals so that they can be used a week each alternately, and disinfected when not in use. This would ensure for the patient a purer atmosphere, which would greatly aid in freeing him from infection. In view of the facts referred to it is doubtful whether a minimum period of retention in hospital of less than eight weeks is sufficient, as I think it safer to increase and maintain the average rather by extending the minimum than by prolonging the maximum period of isolation. With regard to the maximum period I find that several authorities consider thirteen weeks' hospital isolation sufficient even in cases where complications supervene, and irrespective of the healing of discharging surfaces. I incline to agree with this, and think that a minimum of eight with a maximum of thirteen weeks may be considered safe until the contrary be shown, by the result of accurate records based upon careful observation, or they be proved to be incorrect or inadequate by exact bacteriological methods."

The proceedings terminated with a vote of thanks to the President of the section.

OBSTETRICS AND GYNÆCOLOGY.

FRIDAY, SEPT. 3RD.

Two Cases in which Porro's Operation was Performed.

Mr. MAYO ROBSON (Leeds), President of the British Gynæcological Society, read a paper on Two Cases in which he had performed Porro's Operation for Impacted Pelvic Tumours preventing Delivery. In both cases the mother and child were saved and are now well. The first case was one of pregnancy at term, with the pelvis completely blocked by a suppurating ovarian cyst, complicated with a large septic abscess bounded by uterus, ovarian cyst, and intestines. The second case was for pregnancy at term associated with myoma of the posterior and inferior segment of the uterus completely blocking the pelvis. The case had been recently seen, and the remains of the pelvic tumour had completely disappeared. In relating the cases in detail Mr. Robson remarked that where from any cause delivery cannot take place naturally, there are no less than six operations which may be performed to save both mother and child: (1) symphysiotomy, (2) ischio-pubiotomy, (3) complete hysterectomy, (4) laparo-elytrotomy, (5) Cæsarean section, and (6) Porro's operation. In the cases related, where the pelvis was completely blocked by tumours, the two former methods were inapplicable. Total hysterectomy during advanced pregnancy would probably only be resorted to in case of cancer of the uterus on account of the longer time occupied in the technique. Laparo-elytrotomy would have been unsuitable in either, as in one the lower segment of the uterus was involved in the tumour, and in the other the tumour could not have been dealt with had that operation been done. The only methods available, therefore, were Cæsarean section and Porro's operation. Cæsarean section is the operation *par excellence* for obstructed labour depending on pelvic deformity, but in these cases it was out of the question, as in the first instance the tumour so completely blocked the pelvis that drainage of the uterine cavity could not have been effected, and in the second, had the uterus been left, septic trouble must have followed, as the posterior wall of the womb was actually forming the anterior boundary of the abscess sac, and was itself thoroughly involved in the septic process. Porro's operation was, therefore, the only procedure left, and it answered so well that had he other similar cases he would not hesitate to employ it. Moreover, he remarked, it must be borne in mind that Porro's operation can be very rapidly performed and requires only a small armamentarium—important factors in cases of urgency and in emergencies at a distance from a surgical centre.

Spurious Abortion.

Dr. T. W. EDEN (London) then read (by proxy) a paper in which he gave an account of Three Cases of Spurious Abortion. It was an account of a class of cases in which a mimicry of early pregnancy and of abortion occurred, quite different in its characters from the condition known as spurious pregnancy. They were not associated with hysteria and the usual functional disturbances of pregnancy were not exaggerated. They differed from pseudocyesis in the existence of definite changes in the uterus and from pregnancy, either topic or ectopic, in the essential point of the absence of an ovum, either within or without the uterus. They mimicked abortion in the occurrence of a period of amenorrhœa with enlargement of the uterus, and the formation within it of a body, the detachment and expulsion of which was followed by a return to menstrual regularity and the former condition of general health. The body expelled was not an ovum, but was formed entirely from maternal structures. He would describe its exact nature later. A case of this kind had come under Dr. Eden's notice and was communicated to the Obstetrical Society of London. Two other cases had been recorded in the Transactions of the same society, making three in all; but a careful search had failed to show that any such cases had been recorded elsewhere. By the kindness of the reporters of the first two cases (Dr. Griffiths and Dr. Dakin) he had been allowed to re-examine their specimens. A short account was then given of each of these specimens and of Dr. Eden's. In each case there was the same clinical picture of amenorrhœa and morning sickness, terminating after eleven weeks in hæmorrhage and the discharge from the uterus of a fleshy mass, which was at first sight regarded by an experienced obstetric physician as an abortion. Dr. Eden then described the microscopic appearance of the casts, which presented certain points of resemblance to the decidua of pregnancy, with certain well-marked points of difference; in all of them the microscope alone did not suffice to distinguish these casts from those often met with in extra-uterine pregnancy. He would formulate the definition of the condition for which the term "spurious abortion" was suggested as follows: It was "the development within the uterus, in the absence of uterine or extra-uterine gestation, of a membrane having the essential characters of the decidua of pregnancy and accompanied by the signs of early pregnancy; and its separation and expulsion from the uterus with hæmorrhage, thus simulating abortion." Diagnosis was impossible until after the discharge of the cast; it then consisted of two distinct steps—(1) the exclusion of uterine pregnancy by careful microscopic examination of the cast, which demonstrated the absence of chorionic tissues; and (2) the exclusion of extra-uterine pregnancy. In two of the three cases this was possible by direct inspection of the tubes and ovaries, as in each case abdominal section was performed under the impression that the case was one of extra-uterine gestation. Two explanations of the condition were possible: (1) that an ovum was actually fertilised, but perished at a very early period without leaving traces of its presence, while the "genetic reaction" in the uterus and in the general organism progressed as in pregnancy; and (2) that some stimulus other than the presence of a fertilised ovum in the genital tract might lead to the formation within the uterus of a complete decidua, and might hold the menstrual functions in abeyance. Provisionally he adopted the first explanation.

The proceedings terminated with a vote of thanks to the President of the Section.

PHARMACOLOGY AND THERAPEUTICS.

THURSDAY, SEPT. 2ND.

The Treatment of Syphilis.

This section met jointly with the section of Dermatology to discuss the subject of the Treatment of Syphilis. The subject was introduced by Dr. WHITLA (Belfast), who said that two drugs alone need be considered—mercury and the iodides. He regarded it as proved that mercury had a specific or curative effect on syphilis, and thought it best to limit his attention to the following points: (1) how mercury and the iodides were supposed to act; (2) when should mercurial treatment be started; especially should it be given in the primary stage; (3) the various methods for its routine administration, its dosage, and the length of time necessary for mercurial treatment; and (4) the treatment of tertiary symptoms and congenital syphilis. The pharmacology of mercury—the mode of absorption, especially when administered by inunction, elimination, &c.—was considered. Mercury he regarded as a vital antidote to the syphilitic poison, and so long as the virus of syphilis remained in the organism mercury, he believed, would expend its force upon it without injury to the patient. This, he thought, gave a working hypothesis as regards dosage. The question of the bactericidal power of iodides in connexion with Binz's view was dealt with, and their inutility in the first and early second stages emphasised. The continuous and interrupted methods of administering mercury were treated at length, although it was stated that these could not be rigidly separated. The continuous method was favoured by the speaker. He prescribed small doses as early as possible. Routine treatment was deprecated. As a guide determining the effect of the mercury the weight-chart was strongly recommended. Of the various modes of administration the method of inunction was most generally useful, although this posessed many disadvantages. Under ordinary circumstances small doses of mercurous iodides, Plummer's pill, &c., were sufficient. In the tertiary stage Dr. Whitla advised pushing the iodides until the symptoms abated.

Dr. NEVINS HYDE (Chicago) laid particular stress on the constitution of the individual. He believed that there were mild cases needing little or no treatment, and severe cases (mainly inherited) which seemed insusceptible to all treatment. Between these was the mass of cases giving the most satisfactory results. The best effects were obtained where iodides were not used; they were the remedies for the complications.

Mr. MALCOLM MORRIS (London) divided syphilitics into those who took alcohol and those who did not. He had not seen good results from intra-muscular injections. The mercurial air bath in certain conditions (extensive ulcerations) was strongly to be recommended, and to this treatment inunction and warm baths, especially those of a stimulating character, were useful adjuncts. The combination of ammonia and sarsaparilla with iodides was beneficial.

Dr. HERVIEUX (Montreal) spoke of the necessity of definite pathology, a view not shared by some subsequent speakers.—Intra-muscular injections of soluble mercurial preparations were praised by Dr. ALLAN (New York), who also spoke of the virulence of secondary symptoms following extra-genital chancres.

Dr. BULKLEY (New York) thought large doses of iodides unnecessary in the third stage if these drugs were combined with a small amount of mercury.—The President (Dr. LEECH) then closed the discussion by referring to the inutility of other drugs than mercury and iodine, and he agreed with Dr. Whitla in believing it often necessary to push iodides in the third stage of this disease. Combination of the iodides with ammonia was useful.—Dr. WHITLA, in reply, said that the whole secret of success in the treatment of syphilis was to get as much mercury into the system as possible without producing ill-effects. He had not seen one case of harm resulting from the use of mercury in syphilis in his own practice. He criticised Dr. Allan's theory of the virulence of secondary symptoms in cases of extra-genital chancre (the absence of lymph glands in the neighbourhood), and the discussion closed.

FRIDAY, SEPT. 3RD.

The Action of Diuretics.

Dr. JAMES BARR (Liverpool) opened the discussion on this subject. In practice we seek to increase the output of water, hoping that the salines would thus be eliminated also. The theories of renal excretion were considered. The late Sir B. W. Richardson has shown that even enormous pressure is alone insufficient to obtain the water from muscle cells. On the addition of sodium chloride, however, the dry muscle is easily obtained. Dr. Barr considered the question of (1) pressure; (2) volume of fluid; and (3) saline matter in fluid as factors in diuresis. In practice he thought an increase of the quantity of water drunk the chief benefit of watering-places.

Dr. C. R. MARSHALL (Ferndale) went over the theories of renal secretion, using charts to illustrate his remarks. He considered that with physical principles we must also allow the kidney metabolic action. It is as yet unknown how micro-organisms get through a healthy kidney. Secretory nerves, though probable, are not demonstrable in the kidney. In the investigation of diuretics the mistake is often made of assuming an increased flow by reason of a temporary hastening of micturition without increasing the total urine of twenty-four hours. A German writer calls the agents thus acting tachydiuretics. In the classification of diuretics the digitalis group is the only centrally acting one.

Dr. SHINGLETON SMITH (Bristol) said we must take a broader view of dropsies and seek out the numerous factors in the case. Digitalis is the only diuretic all would agree upon. He thought well of apocynum cannabinum.

Dr. D. J. LEECH pointed out the fact that spontaneous diuresis frequently occurred—a fact which helped to give a reputation to many popular remedies.

Dr. A. A. WOODHALL (Denver) read a note on the action of apocynum cannabinum, a milk-weed growing wild in Canada and the States. The tough, fibrous bark is the part used. Its old reputation in dropsies led to name vegetable trocar. He (Dr. Woodhall) was satisfied that it was an efficacious direct renal stimulant and would advise a trial of it.

Dr. A. D. BLACKADER (Montreal) had had experience of the drug in ethereal tincture, and would publish the cases from the Royal Victoria Hospital. Apocynin and apocynein had different actions. The former is an excellent succedaneum of digitalis, the other is an irritant.

Diphtheria Antitoxin.

Dr. H. A. MACCALLUM (London, Ontario) presented a paper relating the results of the use of Behring's serum in cases not diphtheritic. Cases of tuberculosis, sciatica, sarcoma, lupus, and Hodgkin's disease were treated daily for several weeks. The serum he considered as a lymphagogue. Some benefit was claimed in the tuberculous cases, and marked benefit in lupus. In typhoid fever the temperature is first raised, and then lowered. The principal efficacy of serum is that it procures sleep.

Dr. A. T. BAZIN (Montreal) read a paper on the Preparation and Application of Diphtheria Antitoxin, relating his experience in the Montreal Infectious Diseases Hospital. The persons who have been in the vicinity of a case of disease may be immunised by injections, and thus protected by a sort of vaccination.

Dr. J. B. FRASER (Toronto) gave statistics of fatal diphtheria in Toronto: 1894, 9·6 per cent.; 1895, 15 per cent.; 1896, 14 per cent.; 976 cases, average 13 per cent. The feeling was against serum.

Dr. D. J. LEECH had known of collapse after serum, Turbidity of serum is not necessarily decomposition; a little water makes it cloudy.

Dr. BAZIN said that the fluorescent appearance of serum might be mistaken for turbidity; tricresol is the usual preservative for serum.

Dr. M. CHISHOLM (Halifax) read a paper on the Opposite Action of Drugs in Large and Small Doses.

The proceedings terminated with a vote of thanks to the President of the Section.

PATHOLOGY AND BACTERIOLOGY.

THURSDAY, SEPT. 2ND.

Serum Diagnosis and the Agglutinating Action of the Serums.

Professor ADAMI (Montreal) introduced a discussion upon this subject. He referred to the work done by Wyatt Johnston, Welch, Gruber, and Widal, and pointed out that Metchnikoff had experimented on the subject earlier, but

Digitized by Google

that to Widal was due our knowledge of the clinical value of the phenomenon.

Professor MUSSER related his clinical experience of the test, and said that the reaction had been obtained on the seventh day; blood from a case occurring ten years previously had given the reaction; cold baths had not influenced the test.

Professor BOYCE (Liverpool) stated that in Liverpool the distinction between typhus fever and typhoid fever had been made by the serum method. He preferred using fluid serum rather than dried blood.

Professor THOMPSON (New York) summarised clinical experience in five of the largest New York hospitals. He stated that the reaction had been seen on the fourth day of typhoid fever. Attempts to distinguish between typhus fever and typhoid fever by this method had failed; of cases of typhoid fever 75 per cent. were readily diagnosed without this test, 23 per cent. of cases could not be certainly diagnosed by serum methods, and misleading results had been obtained; he therefore claimed that at present this test, like the diazo reaction, was not of great clinical value.

Dr. WYATT JOHNSTON (Montreal), Dr. A. S. GRÜNBAUM (Liverpool), Dr. CABOT (Boston), Professor WESTBROOK (Minneapolis), and others took part in the discussion, which was equally keen on the technique of the method and on its clinical importance.

FRIDAY, SEPT. 3RD.

Infective Swine Diseases.

Dr. V. A. MOORE (Ithaca) made some remarks upon the Nature and Differentiation of the Infective Swine Diseases in the United States. He referred principally to hog cholera and swine plague. There was great difficulty in the nomenclature, but the term "Schweinseuche" seemed to relate to what he understood as "hog cholera." In typical cases there could be no difficulty in differentiating between hog cholera and swine plague. In the United States, where hog cholera was frequently observed, swine plague was rare. He also pointed out the differences in the bacilli of the two affections.

Professor WELCH observed that there was no class of diseases in which there was so much confusion. Metchnikoff's bacillus was not the bacillus of hog cholera, which belonged to the colon-typhoid group, while the bacillus of swine plague belonged to the hæmorrhagic septicæmia type. The American "hog cholera" was identical with the English "swine fever." He concurred in the view that the German "Schweinseuche" is probably the same as swine plague, and pointed out that while the Germans have epizootics of this disease in the United States it is rarer.

Professor ADAMI confessed to having felt some confusion with regard to this subject as he had found in hog cholera bacterial forms with only few flagella, thus differing somewhat from true bacillus of hog cholera. But in view of the statement that animals rendered immune to hog cholera were still susceptible to swine plague he thought that he must regard them as two distinct diseases.

Professor ADAMI then read a paper on

Pictou Cattle Disease.

This was a disease, he said, which had been known for a great number of years and which was found only in a small locality in the neighbourhood of Pictou, Nova Scotia. This disease was characterised by some swelling of the abdomen, slowness in eating or rumination, followed by a paretic condition of the hind legs. The cattle soon lay down and death followed in a few hours. It was noticed to exist only in certain farms and spread to adjacent holdings very slowly. Those regions where the carcases had been buried seemed to be the most likely to contain the contagion. Locally the farmers considered the disease to be due to the cattle eating a plant which was very common in the district and known vulgarly as "stinking willie." There were abundant facts to prove that this was not the case, but he thought that as the stems were very hard the injury to the intestine might result from eating them and so the animal be predisposed to the infection. Post mortem the disease was characterised by very slight alteration of the intestine, with hyperplasia of the abdominal lymph glands, and a cirrhotic condition of the liver. The abdomen regularly contained from two to three pints of clear serum. These conditions had been present in twenty cases which he had studied, with the exception of one doubtful one. All of his cases were advanced, but Dr. W. Johnston had obtained cases at an earlier period, and then there was distinct enlargement of the livers. Dr. Adami had been enabled to isolate the bacillus, which was very small and grew on all media. In inoculation experiments he had been unable quite to reproduce the picture of the cattle disease as the animals died in the early stage before the typical cirrhosis had had time to appear.

Dr. D. MCEACHRAN (Montreal) said that the disease had been known for forty years. The virulence of the infective agency was difficult to estimate, but the disease did not spread rapidly out of the district. Where cattle had been removed from the infected districts and isolated only 1 in 200 was found to develop the disease.

Professor BOYCE asked if the organism was related to the colon group.

Professor ADAMI, in reply, said that it resembled the colon group, but presented minor differences. It fermented glucose, but not other fermentable substances. It was smaller than the bacillus of swine plague and was not vacuolated.

Dr. W. T. CONNELL (Toronto) showed for Dr. KANTHACK and himself specimens of the Tetanus Bacillus stained by the nitrate of silver method to show the flagella. In the early stage the bacillus presented from twenty to thirty very fine and tortuous flagella. In a later stage large thick flagella were developed which might be secondary. Later a single flagellum only remained of a corkscrew shape. When spores began to form the flagella became detached. In the terminal drumstick form they had been enabled to detect in the capsule the remains of the original flagella.

Dr. A. S. GRÜNBAUM showed some Micro-photographs of a case of Pseudo-hypertrophic Muscular Paralysis, in which there was a degeneration of the peripheral nerves in addition to changes in the muscle fibres themselves and thickening of the vascular walls.

Dr. HAMILTON K. WRIGHT (Montreal) read a pape entitled: On the Topography of the Posterior Columns. He reported in detail the anatomical lesions which were found in a very interesting case of tabes dorsalis, with some indications of a terminal acute myelitis.

Tubercle Bacillus in Milk.

Dr. R. BOYCE, Holt Professor of Pathology in University College, Liverpool, then read a paper on the Tubercle Bacillus in Milk, introducing a discussion on the communicability of tuberculosis from lower animals to man. He had, he said, examined 111 samples of dairy milk as supplied to Liverpool. He had found, like others, that the first milk from the cow contained most of the micro-organisms. In only from 5 to 6 per cent. of cases had the colon bacillus been found, and this in small quantity. He had found tubercle bacilli in only four cases out of his 111. Could organisms which had gained an entrance into an animal pass through the mammary gland and appear in the milk without affecting the udder?

Dr. ERNST (Boston) emphasised the necessity of a careful microscopical examination of the udder for tuberculosis, for in one case diagnosed as interstitial mastitis miliary tubercles had been found. A complete examination, however, was by no means easy.

Dr. ABBOTT (Philadelphia) stated that in his inoculations of cattle with diphtheria bacillus he had not been able to find them in the milk, his results being in direct antagonism to those of Professor Klein in England.

Dr. D. MCEACHRAN stated that in every case where the udder was tuberculous the milk was infective.

Professor WELCH stated that one observer who had made a very careful and complete microscopical examination of udders found that in nearly all cases where the bacilli were found in the milk there was miliary tuberculosis in the udders. He also stated that in human milk he had constantly found the staphylococcus pyogenes aureus, or, perhaps better, the staphylococcus epidermidis albus as he preferred to call it, and regarded it as a normal inhabitant of the larger milk ducts in the nipple. So that observations of bacteria being excreted through the milk should be regarded with great care when this coccus was present. He considered it a very peculiar circumstance that when so many acid-forming germs were constantly present in the ducts the milk in the nipple did not coagulate.

Dr. PARK (New York) had found in sucklings a few hours old the staphylococcus albus in pure cultures taken from the oral mucous membrane.

Dr. W. T. CONNELL (Kingston, Ontario), the secretary of the section, also spoke.

Digitized by Google

Professor WELCH (Baltimore) then read a paper on

The Distribution and Pathogenic Effects of the Bacillus Aerogenes Capsulatus.

He described the original case in which Nuttall and himself had found this bacillus at a necropsy on a case of aortic aneurysm. It was found in pure culture, and there existed emphysema of the subcutaneous structures. The blood-vessels and the heart contained abundant gas-bubbles. There was also gas in the pericardium and the peritoneum. The organs all presented the appearance called by the Germans "Schaumorgane." Smear preparations revealed a single species of bacillus, and under anaerobic conditions he got numerous colonies of the same bacillus. It was non-motile, about the size of the anthrax bacillus, anaerobic, positive to Gram, and produced gas on fermentable material. Capsules could be demonstrated. It had first been thought that it was non-sporogenic, but Dunham, of New York, had recently found spores in cultures on blood serum. The pigeon was the most susceptible animal, and inoculations produced extensive necrosis and bloody œdema of the part. By comparing his cultures with those of E. Fraenkel of a bacillus found in gaseous phlegmons the identity of the bacillus aerogenes with the bacillus œdematis phlegmonosæ of Fraenkel had been established. Since then he had studied 41 cases—11 gaseous phlegmon, 1 pneumo-peritonitis, 4 puerperal, 4 gas-cysts, 2 invasion from lung, and 10 others probably cadaveric in origin.

Dr. A. G. NICHOLLS (Montreal) stated that he thought the subject had not attracted the attention in Europe that it had deserved. He stated that he had seen in Vienna cultivations of the bacillus aerogenes which had been found in so-called cases of *gangrène foudroyante*. He thought that many cases of gaseous phlegmon, physometra, and similar conditions should be referred to the action of this bacillus. Some observers had thought that the condition of "Schaumorgane" might be caused by the colon bacillus, but he thought that the etiological relationship of Welch and Nuttall's bacillus to the condition was established beyond a doubt. In the cases he had examined the bacillus coli had been conspicuous by its absence. In view of recent investigations by Chvostek and Morisani we should receive such cases with some reserve until further investigations should be made. He also touched on the subject of mixed infections in these cases

Contagious Pleuro-pneumonia in Cattle.

A discussion on this subject was then opened by Professor ADAMI. In this disease he said the danger lay in the insidious nature of its onset. The course, too, might last from 14 days to several months and the convalescence was often tardy. He referred to the long dispute which had taken place between the veterinary authorities of Great Britain and those of Canada. The Canadians were positive that not one case of true pleuro-pneumonia existed in Canada, but in spite of their representations and protests the Canadian cattle had been scheduled entailing a great loss on the country. On the other hand, it was proved that England had been a centre of infection to the colonies, and the arbitrary action of the Board of Agriculture was not calculated to advance those sentiments of brotherhood and union which so recently formed the basis of many eloquent speeches. It was absurd to doubt the veracity of the Canadian blue-books, for were they falsified the first effects would have been felt in Canada and not in England, and the matter could not have been kept secret.

Professor WELCH agreed with Professor Adami that contagious pleuro-pneumonia did not exist either in Canada or the United States. The gross anatomical appearances of the lungs of typical cases were striking. On the interlobular exudata comparatively few cells are to be seen. Outside this is a zone of disorganized chromatin; outside this, again, granulation tissue. These appearances are seen wherever there are connective tissue and lymphatics.

Dr. MCEACHRAN stated that in Canada to every locality whence the cattle condemned in England had been taken Canadian experts had been sent and failed to find even suspicious cases. He had the authority of the Minister of Agriculture to say that the offer of the Canadian Government to pay the expenses of three experts chosen by England to investigate the subject properly still held good.

The business of the Section was brought to a close by a unanimous vote of thanks to the President.

PSYCHOLOGY.

FRIDAY, SEPT. 3RD.

This section began its work on Friday morning with a thoughtful paper by Dr. T. D. CROTHERS (Hartford, Conn.), on

Some New Phases of Inebriety in Clinical Studies.

He pointed out that from 60 to 70 per cent. of all inebriates were of hereditary origin, their ancestors having been usually of the neurotic type. The abuse of alcohol was often only a symptom of degeneration, so that by removing the spirits we did not always remove the cause of the inebriety.

Dr. BUCKE emphasised the fact that the drink habit in incipient paresis was symptomatic rather than causative.

Insanity in its Relation to the State.

Dr. J. RUSSELL (Hamilton, Ontario) then read a paper on this subject. He held the view that insanity was increasing in the lower classes of society, but not in the wealthier, and that the mass of the lunatics of to-day come from the uneducated class. They were being driven to the wall in the modern struggle for wealth and position.

Dr. DANIEL CLARKE, of the Asylum, Toronto, held that general paralysis came from the better classes, and that syphilis was only one of the causes of it. In his opinion, we should have to come to surgery to stay the present rate of degeneration.

Dr. EDWARD BRUSH (Baltimore) said there could not be a general distribution of wealth that would last, unless there were a general distribution of ability. He denied that the poor man was trodden down in these days. In every way his environment was better than a century ago.

Dr. URQUHART (Perth) stated that epilepsy was uncommon in Scotland, and mentioned the tradition, without asserting that it was true, that in days bygone castration had been performed on this class of cases.

Locomotor Ataxy as a form of Chronic Parenchymatous Degeneration of the Paraneural System.

Dr. VANGIESEN (New York) read an instructive paper illustrated by black-board drawings on this subject. He showed that the growth of our knowledge of the cell, with modern methods of staining, was doing much to unravel the intricacies of mental diseases. He said he thought the alienist in an asylum had a poor opportunity to study the beginnings of disease, as patients go to hospital after insanity has developed. Both the brain and insanity had hitherto been studied too much apart. It is necessary to see how the nervous system is involved in other diseases such as are found in general hospitals.

After a short discussion the meeting closed with a vote of thanks to the President (Dr. R. M. Bucke).

OPHTHALMOLOGY.

THURSDAY, SEPT. 2ND.

The Etiology of Trachoma.

Dr. G. T. STEVENS (New York) read a paper propounding a theory of the causation of trachoma. Relying for his theory upon the fact that trachoma is stated to be more prevalent in certain races presenting a special cranial conformation he conceived it possible that this structural difference might involve a tendency to imperfect equilibrium of the ocular muscles, and in this way the imperfectly protected eye would be rendered more susceptible to infection.

The discussion which ensued did not lend much support to this suggestion, the speakers who followed being more disposed to attach importance to the infective agent itself.

FRIDAY, SEPT. 3RD.

The Hypodermic Use of Pilocarpine in Eye Diseases.

A discussion was opened on this subject by a paper read by Dr. G. H. BURNHAM (Toronto), who described satisfactory results obtained in his practice by the use of the drug.

Dr. FRYOR (Kansas City) said that he had employed pilocarpine in hæmorrhages into the retina and in sympathetic ophthalmia, but that he never gave it in syphilis. He generally prescribed it with an alcoholic stimulant on account of the tendency to heart failure.

Dr. ALT (St. Louis) said that he had had some disagreeable experiences with pilocarpine, and Dr. C. H. WILLIAMS (Boston) advised that a fresh sterilized solution should

Digitized by Google

always be employed, as he had known abscesses to follow injections.

Dr. BURNHAM, in reply, said that he had never given alcohol when using pilocarpine. He guarded against heart failure by keeping the patient well covered up and in bed. He considered women more susceptible to pilocarpine than men.

The Importance to be Attached to Colour-blindness in the Marine and Railway Services.

Dr. W. H. SMITH (Winnipeg) introduced a discussion upon this subject by reading a paper upon it written by Mr. T. H. BICKERTON, Ophthalmic Surgeon to the Liverpool Royal Infirmary.

Dr. C. H. WILLIAMS (Boston) said that two things were necessary upon which Mr. Bickerton laid no stress—the test of colours with wools and the test with transmitted light through small openings.

Dr. MITTENDORF (New York) had control of the New York Central System. His method was to use Holmgren's test, and also to test with signals like those that the employé would have to recognise in his work. He thought that examinations should be held at frequent intervals, and not once and for all.

Dr. ALT said that he had not been able to impress the importance of the question on the management of the Missouri Pacific Railroad.

Dr. RIVERS (Boston) asked if a case of colour-blindness of one eye had been observed, to which the President of the Section, Mr. NETTLESHIP, replied that undoubtedly there were a few cases of monocular colour-blindness, though the condition was a rare one.

Dr. C. H. WILLIAMS said that all men coming into a company should be rigidly examined, and a company which did not do so would eventually be loaded with rejected men from other companies.

Dr. PRUME (Montreal) said that the question would probably be a Parliamentary one at the next meeting of the Dominion Legislature.

Dr. WURDEMANN (Milwaukee) read a paper on Skiascopy in Relation to other Methods of Estimating Ocular Refraction. He showed his apparatus, which was greatly commended by the members.—Dr. C. H. WILLIAMS read an interesting paper on Simulated Monocular Blindness.—Dr. FOUCHER (Montreal) contributed a paper, read by Dr. PRUME, on the Etiology of Dacryocystitis.—Mr. NETTLESHIP showed an instrument devised by Dr. E. P. JONES for irrigation of the lacrymal duct.—Dr. A. PROUDFOOT (Montreal) read a paper on the Value of Weak Lenses in Certain Cases.

The proceedings terminated with a vote of thanks to the President of the Section.

LARYNGOLOGY AND OTOLOGY.

THURSDAY, SEPT. 2ND.

The Significance of Laryngeal Paralysis.

A discussion upon this subject was opened by Dr. W. H. DALY (Pittsburg).

Dr. E. L. SHURLY (Detroit) spoke chiefly in regard to prognosis, specially insisting that structural lesions would be found more frequently in cases of hysterical paralysis if looked for.

Mr. LENNOX BROWNE (London) observed that the term hysterical aphonia was used owing to indolence. He held that aphonia from singing was attributable more to improper use of the voice than to its over-exercise.

Dr. D. B. DELAVAN (New York) insisted on the need of more investigations into right-sided laryngeal paralysis, and referred to two unusually persistent cases of diphtherial paralysis, one of which had lasted for three years and the other for sixteen years, with no return of the vocal powers.

Dr. W. PERMEWAN (Liverpool) referred to certain observations that he had made upon the condition of the larynx in general paralysis of the insane. In this disease abductor paralysis was very common, and he held that a very constant diagnostic sign of hysterical paralysis was the absence of all abductor paralysis. He concluded by relating a case of bilateral abductor paralysis due to pressure upon both recurrent nerves by an aneurysm.

A Case of Foreign Body removed from the Larynx by Partial Thyrotomy.

Dr. CHARLES H. KNIGHT (New York) read an interesting note on a case where a metal shoe hook had been removed successfully from the larynx. The patient was a boy, seven years old. The inspiration of the foreign body was followed by a violent attack of coughing and dyspnœa, which subsided in a few moments. Aphonia and very slight laryngeal stridor persisted. In about ten days after the accident the body was discovered by means of a laryngeal mirror lying in the right ventricle of the larynx, close to the anterior commissure. Numerous attempts at removal with forceps and by means of Kirstein's autoscope both with and without an anæsthetic failed. The external operation was done six weeks after the accident. The incision included the first two rings of the trachea and the lower half of the thyroid cartilage. The operation offered no unusual difficulties and convalescence was prompt. The voice was suddenly restored ten weeks later. Attention is drawn to the absence of serious subjective symptoms and to the importance of making an incomplete section of the thyroid cartilage, in order to ensure accurate re-adjustment of the parts and consequent preservation of vocal function.

Dr. J. N. MACKENZIE (Baltimore) read a paper upon the Physiological and Pathological relation between the Nose and the Sexual Apparatus, implying a connexion that we should be sorry to find many practitioners to consider to exist, though Dr. Fliess, of Vienna, has demonstrated what he terms the "genital places of the nose."—Dr. J. O. ROE (Rochester, N.Y.) read a paper upon the Correction of Nasal Deformities by subcutaneous operations.

FRIDAY, SEPT. 3RD.

An Artificial Larynx.

Dr. ANDERSON STUART, Professor of Physiology in the University of Sydney, Australia, gave a demonstration of an Artificial Larynx which he had designed.[1] In planning his instrument he found that a glottis permitting good respiration was too large for good phonation, and *vice-versâ*. This he avoided by having reeds attached to his instrument to be used only as required for phonation. To ensure comfort he avoided having a complete metal tube, but made a framework of soft rubber, consisting of a soft rubber flat piece to be tied about the neck into which a rubber tracheal tube was inserted and the metallic portion containing the reed fitted snugly into this. Its advantages he claimed to be flexibility, ease of insertion and removal, cleanliness, and comfort. As ordinarily used the respiratory glottis gave very free entrance of air, and if the patient desired to phonate by occluding with his finger the respiratory glottis the air now directed through the reed passed by a specially devised tube upwards into the throat where the resonance chambers could be utilised as in natural phonation. The pharyngeal tube started from the upper part of the tracheal tube, and was devised from a coil of piano wire—being incompressible laterally and longitudinally, but quite flexible—covered with strips of thin rubber, and capped by a small valve of glove leather preventing the return of fluids into the tube. With this instrument a patient was able to converse quite freely.

The Ultimate Results of Operations on the Mastoid Process in Suppurative Ear-Disease.

A discussion on this subject was opened by Dr. F. BULLER (Montreal). He considered only that form of mastoid disease seated in bony structures and spoke of two varieties. First, and most common in adults, was the simple form with no caries or necrosis, in which there were granular cell contents or diffuse inflammation in bone or abscess in bone of the non-fœtid type with thick mucoid pus. Secondly, and most frequent in children, there was a purulent fœtid or ichorous discharge with either caries or necrosis. In the first class he had operated on many and found that after relief recovery had been complete and satisfactory and as a rule hearing had returned to the normal standard. In dealing with the second class he traced out to its utmost limits all inflamed and diseased products and removed them as far as possible; he mentioned his fear of wounding the facial nerve in the tympanum. The prognosis was not as good as in the simple form and hearing was more frequently left impaired. In extension to the cerebral cavity he had seen no good from treatment of pachymeningitis, but mentioned a successful operation for temporo-sphenoidal abscess.—Dr. Arthur H. BUCK (New York) spoke of acute and

[1] A full description of the instrument will be found in THE LANCET of April 17th, 1897.

Digitized by Google

chronic mastoid disease, the former due to invasion by micro-organisms, leading to occlusion of air cells and pent up suppuration. In removing bone he considered that not only should all softened bone be condemned but also that any highly congested purplish bone, even though bleeding, should be removed. He spoke of inflammation in the tip of the mastoid which was occasionally overlooked, but he thought the region above and behind the antrum was most to be feared. The chronic form he considered was due to less pathogenic bacteria.

Dr. CLARENCE J. BLAKE (Boston) then read a paper on the Ultimate Treatment of Mastoid Disease. This was based on a study of seventy-one cases with thirty-seven operations. He divided his cases into three classes: (1) inflammation of the contents of the mastoid; (2) inflammation of the contents and wall; and (3) suppuration in the walls with extension to the neighbouring organs. He spoke of Macewen's statement that American surgeons were afraid of the lateral sinus; he considered this still to be the case, and stated that it should cause less fear than the danger of wounding the facial nerve. Of his operations he divided them as follows: (1) simple cases healed by first intention, filling wound with blood clot, and wound closed; (2) more severe, but wall intact healed by granulation; (3) diseased wall, dura mater exposed; (4) extra-dural abscess; and (5) brain abscess. Dr. Blake closed with a full bacteriological report of all his cases, and showed some curettes which he used.

Dr. H. LEE MORSE (Boston) read a paper entitled "Remarks on the Anatomy of the Mastoid Portion of the Temporal Bone which have a practical bearing on the Operation for Opening the Mastoid," in which he demonstrated by four large diagrams and many photographs the Schwartze and Stacke operations and the relations of the field of operation to the surrounding structures in each case. He also showed eight carefully mounted and coloured bone specimens demonstrating all the different relations mentioned in the paper. He spoke of the necessity of using smaller curettes in operating on children on account of the limited space and softness of the bone.

Dr. A. H. BUCK then read a paper on the Non-operative Treatment of Chronic Suppurative Disease of the Antrum and Vault of the Tympanum.—Dr. F. BULLER followed with the report of a case of mastoid disease with thrombosis of the sigmoid sinus and internal jugular vein.—In the discussion on the subject of treatment of mastoid disease Dr. GORHAM BAKER mentioned twenty cases of brain complications following mastoid disease with fifteen recoveries under surgical treatment. He also spoke of the necessity for a wide opening on the surface of the mastoid for thorough exploration.

Chronic Inter-arytenoid Laryngitis.

Dr. PRICE BROWN (Toronto) reported four cases of this condition, in two of which lactic acid and in the other two nitrate of silver did good. He questioned whether they should be classed as pachydermia laryngis or simple inter-arytenoid laryngitis.—In discussing this paper the PRESIDENT referred to his experience in London, and thought these cases not uncommon. He found alkaline sprays of more service than astringents.—Dr. TROW (Toronto) mentioned similar cases, and Dr. PERMEWAN considered these to be pachydermia laryngis and preferred lactic acid in the treatment.—The PRESIDENT reported having made a microscopic examination and found it simply epithelial.—Dr. DELAVAN showed an electrolytic needle for use in the treatment of such cases.

Dr. H. V. WÜRDEMANN (Milwaukee) read a paper on Phosphoric Necrosis of the Temporal Bone which presented many points of peculiar interest.

The business of the Section then being completed, the PRESIDENT (Dr. Greville Macdonald), in a few well-chosen words, stated that he considered this a record year in the Section of Laryngology, both from the character of the papers and from the number of illustrious participants.

A vote of thanks was accorded to the President.

ANATOMY AND PHYSIOLOGY.

THURSDAY, SEPT. 2ND.

The Relative Efficacy of Chloroform and Ether as Nerve Anæsthetics.

The chief business of the section was the discussion on Anæsthetics, opened before a large attendance by Dr. A. D. WALLER (London), the President of the section. Dr. Waller's remarks were illustrated by experiments and lantern slides. After premising that an isolated nerve, regularly stimulated, gave regular electrical responses, and was thereby a most suitable tissue upon which to examine the modifying action of various drugs, Dr. Waller proceeded to show the comparative action of ether and of chloroform upon the excitability or "electro-mobility" of nerve. The first effect of ether and of chloroform was an augmentation of excitability, the nerve being rendered more "electro-mobile." The full effect of ether and of chloroform was an abolition of excitability, the nerve being immobilised and not responding to stimulation. Under ordinary conditions of experiment the "immobilisation" by ether was complete and temporary, being followed by recovery up to, and beyond, the normal; whereas the "immobilisation" by chloroform was complete and final, there being no recovery. The nerve had been anæsthetised by ether but killed by chloroform.

The gist of the paper was that chloroform acted upon nerve much more powerfully than ether, the inference being that chloroform was not a safe anæsthetic. For the convenience of members wishing to take part in the debate an illustrated summary of Dr. Waller's paper was published in the first issue (Wednesday, Sept. 1st) of the daily journal of the Association.—The paper was discussed by Professor RICHET (Paris), who was strongly of opinion that deaths under chloroform were due to cardiac, and not to respiratory, failure, and that therefore the heart was the thing to watch.—Surgeon-Colonel LAWRIE (Hyderabad, Deccan) followed, and stated his well-known views as to the inferences to be drawn from the experiments at Hyderabad, arguing that over-dosage was alone to be feared and that such over-dosage commonly resulted from irregular and gasping respiration.—Dr. L. E. SHORE (Cambridge) then described the results of experiments by himself and Dr. Gaskell which went to show that chloroform had a direct and primary depressing influence upon the heart.—Dr. GASKELL corroborated the views of Dr. Shore and an animated discussion arose between Surgeon-Colonel Lawrie and Dr. Shore.—Dr. WALLER then replied on the whole discussion and said that the views of the majority concurred with the conclusions he had drawn from his experiments.

FRIDAY, SEPT. 3RD.

The Physiology of the Heart's Beat.

Dr. W. H. GASKELL (Cambridge), in opening a discussion on this subject, said that he had no new facts to bring forward and had seen no reason to alter the views he expressed fourteen years ago—viz., that all parts of the heart were endowed with the power of rhythmical contraction quite independently of the presence of ganglion cells, but varying in degree in different parts. What, then, was the relation of the ganglion cells to the contraction? In his view simply an accidental relation, the heart being regarded as a modified longitudinal bloodvessel, and the ganglion cells remaining in their old situation in the least modified parts of the tube. These results had been entirely confirmed by the recent experiments of Englemann. (The objections to these views raised by Kaiser and others were briefly considered and refuted.) Other workers had confirmed the truth of these opinions as regarded the mammalian heart also. The ganglion cells did not possess any functions other than those which pertained to sympathetic cells elsewhere. They were, in fact, trophic for the post ganglionic nerve fibres, especially of the vagus nerve. Developmentally the cells were also of exactly similar origin as the other efferent ganglionic cells.

Professor PORTER (Boston) said that the crucial point was, Can any part of the heart which is quite devoid of ganglionic cells continue to contract rhythmically for any time? It might be that in the experiments which seemed to give an affirmative answer to this question the heart was really beating rhythmically to some abnormal and constant artificial stimulus. He described experiments he had made which went to show that the above question could be answered in the affirmative and that the objection indicated could be discounted.

Professor HOWELL (Baltimore) said that he had become more and more convinced of the truth of the views expressed by Dr. Gaskell. There were two hypotheses possible: (1) that the heart contracts in response to a stimulus developed by its own metabolism; of this no proof had been offered; and (2) that the stimulus is in the blood itself—i.e., from outside. He had made experiments to try to determine what the substance

Digitized by Google

in the blood might be which acts as a stimulus and considered that it was probably of an inorganic nature and not unlikely a calcium salt.

Professor MILLS (Montreal) criticised many of the statements of the previous speakers. He thought that the heart beat must be attributed to various factors, which vary quantitatively in different animals.

Dr. MELTZER (New York), Dr. MACCALLUM (Toronto), and Professor CARL HUBER (Ann Arbor) having spoken,

Dr. GASKELL briefly replied.

The Section closed with a vote of thanks to the President.

DERMATOLOGY.

FRIDAY, SEPT. 3RD.

Melanotic Conditions of the Skin.

On Thursday the section combined with the section of Pharmacology and Therapeutics. On Friday the proceedings commenced with a paper from Dr. COLEY (New York), who described his experiences in the treatment of several cases of melanotic conditions which had passed on to a malignant stage. He first considered shortly their anatomical and histological peculiarities in their relations to the prognosis of individual cases, and confirmed the general impression as to the extremely irritating effect of pigment occurring in wrong places. He mentioned then his experience of the treatment of these cases, and said that he had found that the antitoxic serums which had been found useful in other cases of sarcoma, especially of the spindle-cell variety, had produced no effect in the melanotic forms of the disease. He advocated the removal of any pigmented tissue in which the slightest sign of activity was becoming manifest.

Dr. J. GALLOWAY (London) followed with a paper describing a rare form of pigmentation of the skin in some respects resembling the melanotic whitlow described by Mr. Jonathan Hutchinson. In this case, however, the pigmentation had commenced on the sole of the foot apart from the nail of the toes, and the first lesion which had been noticed by the patient five years previous to his seeking advice was the occurrence of the repeated blisters on walking; ulceration finally made its appearance. The particular case mentioned had been operated upon; complete removal of the diseased structure had been carried out, and so far no recurrence had occurred. Taking this case as the basis of his remarks Dr. Galloway discussed the significance of pigmentary deposits in the skin in relation to their preceding malignant growths.

The PRESIDENT (Mr. Malcolm Morris) then continued the discussion and entered a strong protest against continual interference with moles or melanotic deposits, and said that when their removal was finally decided on the operation should be conducted with the greatest freedom, and that particular care should be taken to avoid all irritation of the pigmented area either by incision or by subsequent suppuration.

The Plurality of the Fungi causing Ringworm.

Dr. GALLOWAY demonstrated for Dr. COLCOTT FOX (London) a number of beautiful preparations showing the distinctive microscopic and cultural characteristics by means of which it is possible to distinguish different species of the fungi causing ordinary ringworm. Dr. Fox classified these fungi as follows: (1) the species now well known as the microsporon Audouini; (2) the endothrix fungus as mentioned by Sabouraud as one of the species of his division, the trichophyta; (3) the ectothrix fungus as described by Sabouraud; and (4) the faviform fungi. Dr. Fox criticised the descriptions which the French observer had given of the organs of fructification as distinguishing between various species of these fungi, and remarked that he did not consider that the differences observed were sufficiently characteristic or of sufficiently vital importance to help in the formation of new species.

The Section closed with a vote of thanks to the President.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen, having passed the necessary examinations, have been admitted Diplomates in Public Health by the two Royal Colleges:—

Brind, Harry Hanslow, L.R.C.P. Lond., M.R.C.S. Eng.
Edwards, Henry James, L.R.C.P. and S. Edin.
Erskine, Robert, M.D., M.Ch., R.U.I.
Grandy, William Edward, M.B. Trin. Col. Dub., L.R.C.S. Irel.
Hardy, Henry Louis Preston, L.R.C.P. Lond., M.R.C.S. Eng., M.D. Brux.
Hoare, Edwin Stanley, L.R.C.P. Lond., M.R.C.S. Eng.
Home, George, M.D., M.B., C.M. Edin.
Horrocks, Herbert, L.R.C.P. Lond., M.R.C.S. Eng., M.B. Vict., M.D. Lond.
Lawrence, Sidney Cameron, L.R.C.P. Lond., M.R.C.S. Eng.
McCormack, Charles Vincent, L.R.C.P. Lond., M.R.C.S. Eng.
Martyn, Gilbert John King, M.A., M.B., B.C. Camb.
Salter, Alfred, L.R.C.P. Lond., M.R.C.S. Eng., M.D. and B.S. Lond.
Savage, William George, L.R.C.P. Lond., M.R.C.S. Eng., B.Sc., M.B. Lond.
Stanley, Arthur, L.R.C.P. Lond., M.R.C.S. Eng., M.D., B.S. Lond.
Thomas, Daniel Lewis, L.R.C.P. Lond., M.R.C.S. Eng., and L.S.A. Lond.

Six gentlemen were referred to their studies for six months.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates have passed in the subjects indicated:—

Surgery.—J. B. Cautley (Section II.), St. Bartholomew's Hospital; F. M. Cooper (Section II.), Royal Free Hospital; J. F. Fox, Cork and Westminster Hospital; F. R. Greenwood, St. Bartholomew's Hospital; and H. Munro, Guy's Hospital.
Medicine.—E. C. Bailey, King's College Hospital; F. M. Cooper (Section II.), Royal Free Hospital; R. H. Hill, New York and Middlesex Hospital; and A. H. Turner, London Hospital.
Forensic Medicine.—E. C. Bailey, King's College Hospital; and R. H. Hill, New York and Middlesex Hospital.
Midwifery.—E. C. Bailey, King's College Hospital; F. M. Cooper, Royal Free Hospital; C. G. L. Dähne, St. Bartholomew's Hospital; A. J. Hayes, Middlesex Hospital; R. H. Hill, New York and Middlesex Hospital; A. H. Turner, London Hospital; and R. L. G. Worsley, St. George's Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—Messrs. E. C. Bailey, C. G. L. Dähne, J. F. Fox, and A. J. Hayes, and Miss F. M. Cooper.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—At the College of Medicine, Newcastle-upon-Tyne, in the second examination for the degree of Bachelor of Medicine, the following candidates have satisfied the examiners:—

Anatomy, Physiology, and Materia Medica.—First Class Honours: Richard Henry Dix, College of Medicine, Newcastle-upon-Tyne.—*Second Class Honours:* Reginald Alderson, College of Medicine, Newcastle-upon-Tyne; Philip Meyler Perkins, St. Bartholomew's Hospital; Duncan Matheson Johnston, College of Medicine, Newcastle-upon-Tyne; Ralph Tennyson Jupp, Mason College, Birmingham; Frederic William Lambelle, College of Medicine, Newcastle-upon-Tyne; Gerald Burton-Brown, L.S.A., Guy's Hospital; James Robert Burn, College of Medicine, Newcastle-upon-Tyne; and Ernest Frederick Wharton Bywater, Mason College, Birmingham. *Pass List.*—Henry Braund, Guy's Hospital; Bernard Edward Granville Bailey, St. Bartholomew's Hospital; Robert Tilbury Brown, M.R.C.S., L.R.C.P., Guy's Hospital; Richard Henderson Garbutt, Arthur Hines, John MacFadyen, Robert Peart, Thomas Smirk Percival Parkinson, and George Woodyatt Procter, College of Medicine, Newcastle-upon-Tyne; Reginald Percy Richardson, Westminster Hospital; Eleanor Shepheard, London School of Medicine for Women; Leonard Satchwell Smith, Mason College, Birmingham; John Ernest Sidgwick, College of Medicine, Newcastle-upon-Tyne; Alfred Messer Thomas, Guy's Hospital; John Henry Tripe, London Hospital; Richard Thorne-Thorne, St. Bartholomew's Hospital; Thomas John Augustus Tulk-Hart, M.R.C.S., L.R.C.P., Guy's Hospital; Percy Edward Turner, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; and John Charles Velenski, College of Medicine, Newcastle-upon-Tyne.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berne:* Dr. Max Stooss has been appointed Extraordinary Professor of Children's Diseases.—*Breslau:* Dr. Kader and Dr. Kühnan have been recognised as *privat-docenten* of Surgery and Medicine respectively.—*Greifswald:* Dr. Tilmann has been appointed to succeed Professor Heidenhein as Extraordinary Professor of Surgery.—*Marburg:* Dr. A. Schirmer, of Basle, has declined the invitation to the Professorship of Odontology.—*St. Petersburg (Military Medical Academy):* Dr. Rulbin has qualified as *privat-docent* in Medicine.—*Turin:* Dr. Sacerdoti, Dr. Penzo, and Dr. Ferria have been recognised as *privat-docenten* of General Pathology, Surgical Pathology, and Bacteriology respectively.—*Vienna:* Dr. Hugo Wintersteiner has been recognised as *privat-docent* of Ophthalmology.—*Zurich:* Dr. J. Ruge, of Amsterdam, has been

Digitized by Google

appointed Professor of Anatomy in succession to Dr. P. Stöhr.

VACCINATION GRANT.—Mr. F. W. Lewis, M.R.C.S. Eng., L.S.A. Lond., Public Vaccinator of the No. 1 District of the Llandovery Union, has for the tenth time in succession since his appointment obtained the Government grant for successful vaccinations performed.

THE INFECTIOUS DISEASES NOTIFICATION ACT AT ABERDARE.—After a struggle of nearly six years the Infectious Diseases Notification Act was on Sept. 10th adopted at the meeting of the Aberdare District Council by 9 votes to 3. The Act is to come into force on Dec. 1st next.

THE BAKERS' AND CONFECTIONERS' EXHIBITION.—This exhibition, which is to-day (Friday) brought to a close at the Agricultural Hall, Islington, is the fifth of its kind. One of the features of the Exhibition is the model bakery which has been erected at a cost of about £1600. Here the operations of dough-making and dough-dividing by machinery, bread-making, and the manufacture of pastry and confectionery are shown with the object of proving that the underground bakeries of the Metropolis are totally unnecessary.

PRESENTATION TO A MEDICAL MAN.—Mr. Robert I. Stevens, M.R.C.S. Eng., who has practised in Hoddesdon and district for upwards of forty years, on his retiring from practice, has been presented with a testimonial, the subscriptions for which amounted to about £260, contributed by nearly 300 residents. Out of this sum an annuity of £30 per annum was purchased, and on the 10th inst. he was the recipient of a deed conveying the annuity to him and a cheek for the balance, with an album in which the names of the contributors are inscribed.

THE SEWAGE DIFFICULTY AT MANCHESTER.—At the last meeting of the City Council the culvert scheme was passed by a vote of 49 to 9. But Mr. Norbury Williams, one of the elective auditors of the city, put in a protest against this decision, as 49 was not a majority of the whole council, 53 being required, since according to the Borough Funds Act no costs for promoting any Bill in Parliament can be charged on the city funds unless incurred under a resolution of an absolute majority of the council, to be confirmed by a ratepayers' meeting. The matter will, therefore, be brought up again at a meeting of the council to be held probably on Oct. 6th.

THE NEW MEDICAL DEFENCE ASSOCIATION, LIMITED.—At a meeting of the directors of this association held on Sept. 17th it was resolved to assist a member in an action brought against him, the cause of action arising from the fact that he had certified an infant's death as due to "hereditary syphilis." Dr. Leslie Phillips reported that the books were in the hands of the auditors, and that the accounts and report for the past year would be issued in the course of a few weeks. The accounts would again show a substantial increase to credit, and the cash position of the association, he believed, would allow the reduction of future annual subscriptions to 5*s*. instead of 10*s*. as at present.

DIPHTHERIA IN LONDON.—There were registered last week in the county of London 35 deaths from diphtheria, a number 10 in excess of the total of the week preceding, and identical with that of the week ended Sept. 4th. It was, however, 6 below the corrected decennial average for the corresponding weeks of the years 1887-96. Camberwell is credited with 5 of the deaths, and Battersea and Wandsworth sanitary areas each with 3 deaths, the northern and western groups of districts registering 18, and the central, eastern, and southern groups 17 deaths. Nineteen of the deaths were of children under 5 years of age, including 2 of infants, and only 2 were of persons aged over twenty years. The admissions to hospital in the week were 156, against 121, 131, and 140 in preceding weeks, and on Saturday last there were just 1000 patients under isolation and treatment for the disease. In the outer ring as many as 19 deaths from diphtheria were registered, of which 5 were registered in West Ham district, and 3 occurred in Edmonton district. Thus there were 54 deaths registered from the disease in "Greater London," with upwards of six millions of people, as compared with 12 in the other five millions of people in the remaining thirty great towns of the Registrar-General.

THE HEALTH OF BOMBAY.—We are glad to be able to report that the general mortality at Bombay is declining, although it still remains in excess of the normal amount. The deaths are mainly attributable to fever, dysentery, and cholera, although the last-named disease seems to have been decreasing during the past four weeks.

THE WOMEN'S HOSPITAL AT REDRUTH.—Mr. Passmore Edwards has promised to erect a new wing to the Women's Hospital at Redruth for the accommodation of sick children. This will be much appreciated by the industrial classes of West Cornwall. Details of the suggested addition will shortly be laid before the subscribers.

SANITARY MATTERS IN GLAMORGANSHIRE.—At a meeting of the Glamorganshire County Sanitary Committee held on Sept. 10th the sub-committee appointed to consider the question of establishing a laboratory for the department of public health reported in favour of such an institution. At this laboratory chemical and bacteriological examinations of water, sewage contamination, diseased tissues, &c., will be made. The advantages that will arise from such an establishment are obvious. The sub-committee of the Glamorganshire County Sanitary Committee have recommended that the salary of their medical officer of health should be increased to £800 per annum.

BABY FARMING AT STRETFORD.—A man and his wife were charged the other week at the Manchester county police-court with an offence under the Infant Life Protection Act at Stretford. Two infants were taken in to nurse, and one died at seven weeks old, having been in the charge of the defendants for three weeks. According to the Act all houses where more children than one were taken care of for more than twenty-four hours at a time should be registered. The defendants had not done this. There was no suggestion of ill-treatment. Five shillings weekly were paid with each child. The magistrates imposed a penalty of 5*s*. and costs, which came nearly to 30*s*. The male defendant said he would have no more children at his house.

THE LIFE SAVING SOCIETY'S HANDBOOK OF INSTRUCTION.—This useful little book has been specially prepared for teaching those able to swim how best to rescue persons in danger of drowning; if clutched, how to effect a release; and how to resuscitate the apparently dead. It deals with the theory of circulation, respiration, and resuscitation, and explains fully all the methods of rescue, &c., as set forth by the society. The book is interesting and is of great use to the swimmer. It is pleasing to be able to state that as a result of the many classes of instruction that have been held in all parts of the United Kingdom many cases of rescue by members have been reported this season.

LITERARY INTELLIGENCE.—Messrs. Baillière, Tindall, and Cox will publish next week a work on "Heart Disease," by Sir Wm. Broadbent, Bart., M.D., F.R.S. The publication has been delayed on account of the many calls on the author's time. They will also publish a new work on "The Roentgen Rays in Medicine and Surgery," by Dr. Walsh and Mr. Greenhill; a work with coloured plates on the "Essentials of Bacteriology," by Professors Lehmann and Neumann, with English translation; a handbook on "Air, Food, and Exercises," by Dr. Rabagliati; one on "Diagnosis," by Mr. Parkinson; and a new edition of Mr. Symons Eccles' work on "Massage."—"A Manual of Hygiene for Students and Nurses," by John Glaister, M.D., D.Ph. Camb., Professor of Forensic Medicine and Public Health, St. Mungo's College, Glasgow, will shortly be issued by the Scientific Press, Limited.—Messrs. J. & A. Churchill announce that they will publish on Oct. 1st a third edition of "Elements of Human Physiology," with several new illustrations, by Ernest H. Starling, M.D., F.R.C.P. Lond., Joint Lecturer on Physiology at Guy's Hospital; and an eleventh edition of "A Manual of Minor Surgery and Bandaging," by Christopher Heath, F.R.C.S. They also have in the press a work on "Maternal Syphilis, including the Presence and Recognition of Syphilitic Diseases in Women," with illustrations, by John A. Shaw-Mackenzie, M.D. Lond.

Appointments.

Successful Applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ANDERSON, J. LINDSAY, M.B., C.M. Glasg., has been appointed Dispensary Assistant Surgeon to the Royal Hospital for Sick Children, Glasgow.

BETHELL, A., M.R.C.S., has been re-appointed Medical Officer of Health by the Bridgnorth Rural District Council.

BURNETT, L. B., M.B., B.S. Camb., L.R.C.P. Lond., M.R.C.S., has been appointed a House Surgeon to the Royal South Hants Infirmary.

CHITTENDEN, T. HILLIER, M.D., M.R.C.P., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

COATES, B. O., M.D., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

COUNIHAN, RANDAL, Dr., has been appointed Medical Officer of the Kilrush Union Hospital, vice J. E. Foley, resigned.

DAVIES, J. H., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of Health for the Northern Sanitary Division by the Wrexham Rural District Council.

FRASER, H. E., M.A., M.B. Edin., has been appointed Medical Superintendent to the Dundee Royal Infirmary, vice Nathan Raw, resigned.

GALLOWAY, A. F., M.B., C.M. Glasg., has been appointed House Surgeon to the Royal Hospital for Sick Children, Glasgow.

GRAHAM, W., M.D. Irel., L.R.C.S. Edin., has been appointed Resident Medical Superintendent for the District Lunatic Asylum, Belfast, vice A. S. Merrick.

GRAVELY, W. H., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer for the Cowfold Sanitary District of the Horsham Union.

HART, A. E., M.B., B.Ch. Camb., has been appointed Medical Officer for the Drypool Sanitary District of the Soulcoates Union.

HARTLEY, REGINALD, M.D., F.R.C.S., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

HITCHINS, FREDERIC C., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Assistant House Surgeon to the Royal Hants County Hospital, Winchester.

HOFFMEISTER, WILLIAM, M.D. Heidelberg, L.R.C.P. Lond., M.R.C.S., has been re-appointed Port Medical Officer of Cowes by the Cowes Port Sanitary Authority.

HOSEGOOD, S., M.R.C.S., has been re-appointed Medical Officer of Health by the Swinton and Pendlebury District Council.

O'CONNOR, J. E., M.B., B.Ch. Irel., has been appointed Medical Officer of Health for the Port of Lowestoft.

O'DRISCOLL, Dr., has been appointed House Surgeon to the Cork Mercy Hospital.

RUSHTON, J. L., M.D. St. And., M.R.C.S., has been re-appointed Medical Officer of Health by the Macclesfield Rural District Council.

SUMPTER, EUSTACE WYATT, M.B., B.S. Durh., has been appointed House Surgeon to the West Norfolk and Lynn Hospital, King's Lynn.

TEAGUE, D. G., M.B., C.M. Edin., has been appointed Fourth Resident Medical Officer to the Sussex County Hospital, Brighton, vice F. H. Sturdie, resigned.

THOMAS, D. L., L.R.C.P. Lond., M.R.C.S., has been appointed a Medical Officer by the Limehouse District Board of Works.

TORRENS, J., M.D., M.S., L.R.C.S. Irel., has been appointed Medical Officer for the Tynsall Sanitary District of the Seisdon Union.

WICKHAM, H. T., M.D. Edin., has been appointed Medical Officer for the No. 10 Sanitary District of Newport Pagnell.

WIGHAM, W. H., M.B. Durh., M.R.C.S., has been appointed Medical Officer for the Tenth Sanitary District of the Barnstaple Union.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (27th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (28th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (29th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.).

THURSDAY (30th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.).

FRIDAY (1st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (2nd).—Royal Free (9 A.M. and 2 P.M.), Middlesex, (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

LECTURES, ADDRESSES, DEMONSTRATIONS, ETC.

WEDNESDAY (29th).—CITY ORTHOPÆDIC HOSPITAL (Board Room, Hatton-garden, E.C.).—5 P.M. Mr. Noble Smith: Some Typical Forms of Curvature of the Spine.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1897, which was completed with the issue of June 26th, was given in THE LANCET of July 3rd. It is intended, in future, to include the Index and Title-page for each past half-yearly volume in the first number of the succeeding volume, as in the present case, instead of in the last number of the volume itself, as heretofore.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1897 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

ATTACK OF WITCH DOCTORS ON MEDICAL MISSIONARIES IN RHODESIA.—THE *Edinburgh Evening Despatch* of the 17th inst. gives an account of the attack of native witch doctors on Dr. and Mrs. Owen, of Zimunya, Rhodesia, where they had established themselves for medical missionary purposes. Zimunya is a lonely station, consisting of three huts and a tent on the summit of a high mountain in Mashonaland, about twenty-five miles from Umtali. Staying with them was a friend, the Rev. L. M. Caulfield, of Umtali, who fortunately had brought with him his collie dog. About four in the morning they were all roused by the barking of the dog, only to find the witch doctors making a fierce attack on the mission-house. Dr. Owen fired at the miscreants, but they made a hasty retreat, and unfortunately escaped. It was then found that the dog had been killed by the blow of an assegai. The Rev. Mr. Caulfield attributes the attack to the jealousy of the native witch doctors, who for many generations have attended the sick, and, it would seem, have been well paid for their services—sometimes, it is said, to the equivalent of £4 or £5 a case. They found their occupation gone and their reputation eclipsed by the enlightened treatment of Dr. Owen, for which no charge was made. It is inevitable that in Africa, as elsewhere, the witch doctor must be superseded by the educated physician, and we congratulate Dr. and Mrs. Owen on the happy ending of what might have been a serious disaster. We are not entirely without sympathy with the superseded local practitioners. They upheld the dignity of the art in one respect—they charged for their services, and it is open to them to say that their successful competitor owed his success rather to the fact that his advice was gratuitous while theirs was not. The missionary uses of medicine are most legitimate and beneficent, and in the case of the poor they must be applied without money and without price, but the more free from pauperising abuse it is the better. If the natives can pay, as apparently was the case with many of the people there, they should be required to do so. In introducing the virtues of religion into barbarous countries we must try not to introduce its vices.

Lungs.—We do not know of any book. Our correspondent should make inquiry locally.

WANTED A HOME.

To the Editors of THE LANCET.

SIRS,—I shall feel much obliged if any of your readers can inform me of an institute where a patient of mine can be placed as a permanent voluntary boarder. He is about sixty-five years of age, but mentally weak, not troublesome in any way, but nervous and despondent. His means are small, about 30*s.* per week.

I am, Sirs, yours faithfully,

Sept. 16th, 1897. H. N. W.

A RAILROAD HOSPITAL CAR.

A NEW hospital car has been built for the Long Island Railway Company, U.S.A., under the supervision of Dr. Valentine, chief surgeon to the company. In exterior appearance it resembles an ordinary Pullman car, but the internal arrangements are adapted to the needs of those who may be the victims of a railway accident. The car is fitted with seventeen cots, while in emergency hammocks can be swung from the ceiling; there is also a fully equipped operating room. The car is to be kept always in readiness for despatch to the scene of any accident that may unfortunately occur.

Mr. S. Gross.—"Text-book of Chemical Physiology and Pathology," by W. D. Halliburton, M.D., B.Sc. Lond. London: Longmans, Green, and Co.

"A CASE OF HEMICHOREA WITH APHASIA."

To the Editors of THE LANCET.

SIRS,—Dr. S. J. Ross, in THE LANCET of Sept. 18th, reports upon a case under the above heading. The clinical history is most interesting and raises anew a vast and much-trodden subject for discussion. Following the history come Dr. Ross's remarks upon the pathology and treatment, Gowers's theory of "lowered resistance on the part of the cerebral cells," and the "neurogliosis" theory of other authorities being submitted as the possibly true pathological cause; and, for treatment, *arsenic* is exalted by Dr. Ross as an absolute control power over course and symptoms—"a control which no other drug possesses." In justice to Dr. Ross I must add that he makes exceptions, and names chloral hydrate and bromide of potassium in the early stage treatment of convulsive or epileptiform varieties of chorea. The patient, a girl aged fourteen years, with a *rheumatic history* and a *well-marked mitral regurgitation*, is thrown from a cart. A few days later appear the following symptoms: "Marked cerebral instability ..... Dilated pupils ..... marked choreiform movements of the right arm and leg. Right knee-jerk exaggerated, left being normal. Sensation normal. Cardiac irregularity, mitral systolic murmur, and accentuated pulmonary second sound. Aphasia." These symptoms were successfully treated by arsenic and rest, and in six weeks the girl had recovered her speech power. Now, I submit, is "lowered cell resistance," or even "neurogliosis," a satisfactory or sufficiently clear an explanation of these symptoms? Or, again, is the statement that arsenic possesses over these symptoms "a control which no other drug possesses" to pass unchallenged? Without undue partisanship might one not point to this case as favouring Dr. Kirke and Dr. Hughlings Jackson's theory—"embolism"? Here we distinctly have cause and effect: (*a*) valvular incompetence, with, in all probability, old endocarditic vegetations; and (*b*) shock, displacement of vegetation and embolism, followed by definite cerebral symptoms. Now comes our "lowered cell resistance"—our "neurogliosis," which, passing through a definite six weeks' stage, ends in convalescence. Your space will not permit me to combat or quote the many hypotheses on this subject; but Dr. Ross's case seems so confirmatory of the "embolic" theory that I venture the above criticism. Of the value of arsenic in these cases there can be no dispute. It possesses undoubted powers over chronic "rheumatism," of "malarial" origin especially. But what about the salicylates? In chorea with endocarditis I have rarely failed to obtain definitely successful results with salicylates of soda; but, as I remarked in THE LANCET some years ago (July 9th, 1892), my experience was in the chorea of children and not in adults; and, finally, after all our arguments in favour of rheumatic, i.e., endocardial, embolism, "lowered cell resistance," "neurogliosis," &c., of what pathological significance have those cases of induced chorea—if I may so term them—where from the mere presence of one case in a children's ward others will arise, *de novo*, among the neighbouring children? I am well aware of the anatomical difficulty in supporting the "embolic" theory, and, also, having had in other days the immense advantage of Dr. Howship Dickinson's teaching, am aware that my much respected master held his own theory, "the widely spread hyperæmia of the nervous centres ..... induced by the 'rheumatic' condition," independently of any mechanical mischance. These (Dickinson) vascular changes and induced sclerosis accounting for the wasting, rigidity, and permanent paralysis. In view of all these theories, facts supported by clinical observation, such as in Dr. Ross's case, are of much value in elucidating the truth of this interesting pathological problem.—I am, Sirs, yours faithfully,

HUGHES REID DAVIES, M.R.C.S. Eng., L.R.C.P. Lond.
Bow, E., Sept. 20th, 1897.

Dr. Leopold Mayer is thanked for his offer, of which we are unable to avail ourselves.

QUINE'S PATENT SANITARY ASHBIN.

WE have had brought to our notice this useful backyard sanitary appliance, which was exhibited at the Sanitary Conference at Leeds, where it met with deserved approval. It is designed to obviate uncleanliness in and around the spaces where the ashbin is commonly kept. It consists simply of a scuttle let into a wall, which on releasing a bolt will tilt and discharge its contents outside into a barrow or cart for removal. The bin may thus be emptied without the dustman entering the yard at all and is closed to the outside until it is so tilted. The method is admirable, as it prevents the distribution of dust and garbage during the act of removal in the open spaces around the house, and the inconvenience of the scavenger coming into the house or yard is done away with. Objectionable smells arising from the accumulation of house refuse in this manner are avoided. The appliance is made by the Pendleton Sanitary Engineering Company, 1, Leaf-square, Pendleton, Manchester.

THE STERILISING OF DENTAL APPARATUS.

To the Editors of THE LANCET.

SIRS,—I had recently occasion to take a child, aged eleven years, to a dentist for the removal of a tooth. Gas was administered, and the child returned home apparently all right. The next morning the mother called on me and stated that the child had passed a rather restless night, and had some slight difficulty in swallowing, but did not seem feverish. I made a visit in the evening and examined the child's mouth. The wound in the gum was healthy, but there was a small, yellowish patch on the left tonsil which I had no hesitation in pronouncing to be diphtheria. On inquiry I elicited that the patient had felt her throat a little "sore" on the night previous to her having the tooth out. I called on the dentist and warned him of the case. Had this patient diphtheria at the time of her visit to the dentist? If so, then one can see what a potent source of infection the forceps, mask, tumbler, &c., can become, more especially in the case of children, unless they are thoroughly sterilised after each operation, and it is with the intention of putting dentists on their guard that I send notes of the case.

I am, Sirs, yours faithfully,
Sept. 21st, 1897. MARCUS GLANVILLE.

P.S.—I have just heard that the child has died in hospital from paralysis.

THE X RAYS AND THEIR APPLICATION IN DENTISTRY.

DR. W. J. MORTON recently read an interesting paper on this subject and exhibited a number of skiagraphs before the Odontological Society of New York. He believes that the x rays will be found of great value in diagnosis and open up a wondrous field for investigation and study. He says: "Each errant fang is distinctly placed, however deeply embedded within its alveolar socket; teeth before their eruption stand forth in plain view; an unsuspected exostosis is revealed; a pocket of necrosis, of suppuration, or of tuberculosis is revealed in its exact outlines; the extent and area and location of metallic fillings are sharply delineated, whether above or below the alveolar line. Most interesting is the fact that the pulp-chamber is beautifully outlined, and that erosions and enlargements may be readily detected." Many of these points are clearly shown in the reproductions of the skiagraphs in the *Cosmos*. We can readily believe in the utility of the x rays in dental surgery; thus in the case of a fang of a tooth having been forced into the antrum during an effort at extraction, it is often with the greatest difficulty that it is localised by means of the probe.

A NEW DEPARTURE IN JOURNALISM.

SUBSCRIBERS to *Le Temps* living in Paris are privileged to take part in the x-ray conferences with experiment which are held periodically in the offices of that journal. It is, of course, well known that, thanks to Professor Roentgen's discovery, many opaque things are rendered transparent, so any doubter who has been unfortunate enough to pass under the surgeon's hands for fracture can now satisfy himself that his case has been treated properly. On a late occasion M. A. Rémond, the engineer who is in scientific charge of the x-ray machine for the proprietors of *Le Temps*, presided at what may be called a surgical-control *séance*, when several individuals whose limbs had been broken and duly "set" *secundum artem* by qualified men came forward in order to have their fears either confirmed or allayed. There was, of course, no need to loosen bandages or remove splints; the searching rays pierced through these flimsy appliances with the utmost ease, and apparently all was found to be in order, for the record says nothing to the contrary.

A GYNÆCOLOGIST'S LOCUM TENENS.

MEDICAL men returning home from a holiday are fortunate if they do not find that something has gone wrong with their practice during their absence. It is to be hoped, however, that none of our readers—many of whom are doubtless just now returning from abroad or from the country—may hear of such a very unpleasant fraud as that which has been perpetrated on Dr. Tauffer, professor of gynæcology in the University of Budapest, and his patients. During the professor's absence a country farmer brought his wife for advice. In the ante-chamber they saw a very solemn-looking gentleman of aristocratic mien, who, on their inquiries for the professor, informed them that he was the professor himself. He then listened to what they had to say and examined the patient, informing her that there was nothing very serious wrong. His fee, he said, was 10 gulden, which was paid. The next day the worthy couple bethought them that 10 gulden was a good deal for a single consultation and that they might as well have another for their money. On arriving at the professor's house whom should they see but the great man himself, who had so impressed them the day before, chatting familiarly with a cabman on his box. He did not, however, await them outside, but discreetly betook himself indoors. On coming up to the cabman the farmer remarked that he did not know the eminent professor could be so familiar. His surprise may be imagined when the cabman gave him a contemptuous look and said, "That isn't the professor; that's his butler." Of course, after this there was no more thought of a consultation—of a medical character, at least. The farmer wanted his 10 gulden back and sped to the police station, the result of his visit being that the butler was safely lodged in prison. It was then discovered that during his master's absence the butler had seen, examined, and taken fees from quite a number of patients, chiefly, of course, gynæcological cases. What the Hungarian law courts will have to say to such a proceeding remains to be seen. What the patients think of the matter may be imagined rather than described.

CONNAUGHT AS A HEALTH RESORT.

To the Editors of THE LANCET.

SIRS,—Now that winter is approaching a great deal is being written in THE LANCET and elsewhere about sanatoria and health resorts. The worst of these health resorts is that they are too far away, and are practically useless for the vast majority of invalids residing in Great Britain; besides, I am not aware that these so-called health resorts have ever been tested by a registrar-general. Health resorts and sanatoria to be of any use must be near at hand and easy of approach. It must have struck readers of THE LANCET who have perused the report of the Registrar-General of Ireland for 1896, lately issued, that the Green Isle is a salubrious place, especially the province of Connaught, the mortality of that large district of country being only 12·3. Now, I think there are few health resorts the wide world over that can show so favourable a bill of mortality as this. Connaught, it will be remembered, signifies the country possessed by the children or posterity of Con. Con—commonly called Con of the Hundred Battles—was monarch of Ireland in the second century of this era. The more ancient name of Connaught, however, was Olnegmacht, so-called from Olnegmacht, an ancient Queen of the Firbolgs. The country is noted for its varied and beautiful scenery, its numerous relics of long past ages, and for the important events which have occurred there. Old annalists tell us that the first colony that settled in Connaught was the Parthalanians, from Parthalon, their leader. Then followed the Firbolgs; after these the Inatha De Danaans, and subsequently the Milesians under the three Princes—the three brothers, Heber, Heremon, and Ir. The Milesians soon dominated Connaught as well as all Ireland. All these colonies were Scythians or Celts and spoke the same Celtic language, as did also the ancient Gauls and Britons. The Milesians invaded Ireland about a thousand years before the Christian era. The Inatha De Danaans, the predecessors of the Milesians, were a highly civilised people, skilled in arts and sciences, and possessing some knowledge of the healing art. O'Brien considers that the Round Towers were built by them for pagan worship and astronomical purposes. The Danaans gave the name of Inis Fail to Ireland, signifying the Island of Destiny, from a remarkable stone brought with them into Ireland called Lia Fail, or Stone of Destiny. For upwards of sixteen centuries the Kings of Ireland, sitting on this stone, were crowned at Tara, but in the sixth century the Lia Fail was lent by the Irish monarch for the coronation of his kinsman, Fergus, King of Scotland. The stone was never returned to Ireland, but was kept at the Abbey of Scone until it was brought to England by Edward I. and placed in the coronation chair in Westminster Abbey, where it now rests.—I am, Sirs, yours faithfully,

WILLIAM O'NEILL, M.D. Aberd., M.R.C.P. Lond., &c.

Lincoln, Sept. 13th, 1897.

A WANDERING NEEDLE.

A CORRESPONDENT has submitted to our notice the following interesting case: "The patient," he writes, "a woman, aged about thirty-five years, came into the surgery on the morning of Sept. 7th saying she thought she had a needle in her *left* arm. On examination I had not the slightest difficulty in ascertaining that such was the case, for I could feel the needle distinctly. It was lying in an oblique position in the forearm, near the wrist; the one end of it could be felt anteriorly and the other posteriorly. Consequently I had not much difficulty in extracting it. It proved to be a fairly stout needle with the eye end of it broken off, and measured just over one and a half inches in length. She gave the following history. Twelve months ago she trod upon a needle with her *right* foot, but it was not extracted. Her foot gave her little or no pain until about three months ago, when she thought she felt the needle there. She went to the General Hospital, Birmingham, and a skiagraph of her leg was taken, but nothing could be found, which can now be easily explained by the fact that by that time it must have left the leg. The extraordinary feature of the case is that the needle should pass from the right foot to the left forearm without causing the patient more inconvenience than it did." We agree with our correspondent that the case is an extraordinary one. The travelling proclivities of needles have often been manifested, but never in quite so striking a manner. How does our correspondent know that he extracted the same needle as previously entered the patient's leg?

Mr. G. Careles.—Our correspondent will probably find that Squire's "Companion to the British Pharmacopœia" will help him. There are also some very useful hints in Martindale's "Extra Pharmacopœia." "Selecta e Prescriptis" did not, so far as we remember, contain information on dispensing, except as to terminology, but chiefly formulæ.

ERRATUM.—Dr. A. E. Wright informs us that the sentence, "What is our measure of the alkalinity of *the* fluid which does not contain free *salts*" (col. 1, line 27, page 719), should read: "What is our measure of the alkalinity of *a* fluid which does not contain free *bases*."

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

THE ACTION AND USES OF SOME NEW SYNTHETIC REMEDIES.

LORETIN.

(META-IODO-ORTHO-OXYQUINOLINE-ANA-SULPHONIC ACID.)

The search for antiseptics has been conducted along various lines of investigation, and many substances differing greatly in chemical composition have been accredited with antiseptic properties at different times. Many of these have had an extended sphere of usefulness since Lister first began his epoch-making researches at the Glasgow Royal Infirmary. It will be remembered that in the early days, Phenol was the antiseptic almost exclusively employed in surgical work, but the irritation caused by its poisonous properties frequently set up the very conditions which it was desired to avoid. It has been found that Carbolic Acid is liable to become absorbed and thus to have a deleterious effect on the tissues of the body. At the same time that it kills the bacteria which produce the pathological conditions, it destroys the albuminous structures, thus neutralising its good effects in other directions.

The suitability of any substance as an antiseptic depends as much on its effect upon the tissues and its poisonous action if absorbed as upon its bactericidal properties. An antiseptic of the highest degree of excellence should be sparingly soluble, free from markedly irritant action, and not powerfully toxic. The toxic disadvantages of Carbolic Acid have induced many eminent surgeons and chemists to endeavour to discover a disinfectant that would combine all the advantages with none of the disadvantages of Carbolic Acid. The combinations of Iodine with coal-tar groups have been closely investigated because of the powerful antiseptic properties of Iodine. Iodoform was a useful offshoot from these researches. As an antiseptic it is not so powerful as Carbolic Acid, and in many cases it has proved quite as dangerous. Many surgeons now use it diluted very considerably with Boric Acid, and so endeavour to obtain its antiseptic effects without its toxic results. Iodoform has the great advantage over liquid antiseptics that, owing to its application as a powder, its action is maintained for a length of time without the intervention of any dressing. It falls short of the ideal antiseptic in two particulars, however. Its unpleasant smell is a great drawback to its use, and when it is absorbed, as it readily is, free Iodine is liberated, and symptoms of Iodism and gastric disturbances accompanied by nervous symptoms, such as loss of memory, sleeplessness, and headache, are liable to be produced. Its effect on bacteria, however, is not powerful unless it is employed in rather large quantities.

Several other preparations of a similar character have been tried to overcome these disadvantages, but the objection to all of them has been that they are either too weak in their antiseptic, or too strong in their toxic, properties. When two phenol groups have been combined it has been found that while the substances so formed have retained their antiseptic power, their toxicity has been lessened. The sulphonic compounds are special examples of this, but, with the exception of Loretin, they all have their attendant disadvantages.

Loretin is a Sulphonic Acid preparation of Iodine in combination with Quinoline, yellowish in colour, odourless, and soluble in water to the extent of only a little over 2 p/m. Its power of absorption into the system when applied to wounds is thus very limited, and consequently it has no toxic action. It is perfectly bland in its action on the skin, and instead of producing any eczematous or erythematous condition, has been found, when used as a dusting powder, a very suitable antiseptic application for the relief of these disorders. Its purity can be relied upon and it does not decompose except in the presence of chlorine, bromine, and certain decomposing organic substances. Symptoms of Iodism have never been observed during or after its use. *It is absolutely free from odour of any kind*, although it acts as a deodorant in a very effective manner.

Its antiseptic action has been demonstrated on various forms of pathogenic microbes. Thus the 2 p/m aqueous solution prevents the growth of the bacillus anthracis, bacterium coli commune, staphylococcus pyogenes aureus, and streptococcus erysipelatis. It can be applied undiluted or mixed with suitable vehicles. With collodion it forms a splendid combination and it blends readily and uniformly with Lanoline, or other ointment bases.

Loretin is a perfectly bland, unirritating, and efficient antiseptic agent. It produces salts when combined with sodium, potassium, or calcium, and these may be used for the preparation of Loretin gauze, which can be employed for dressing wounds. It is perhaps one of the best agents that can be employed for treating septic wounds such as those of compound fractures or suppurating sores. For use in solution it may very conveniently be employed by placing a quantity at the bottom of a large bottle and adding water. Occasional agitation will ensure the formation of a saturated solution of a strength of ·2%, a solution of very general utility in every variety of antiseptic surgical practice. The undissolved powder sinks to the bottom and is dissolved by subsequent additions of water. Loretin possesses properties of quite an exceptional character, and can be employed wherever the action of an effective, safe, and reliable antiseptic is required. Its manifest advantages of freedom from odour and absence of toxic effects ensure its very wide use as a substitute for Iodoform.

Supplied to the medical profession in 1-oz. and 4-oz. packets at 1s. 3d. per oz.

ANTIPYRIN (KNORR).

(PHENYL-DIMETHYL-PYRAZOLON.)

Antipyrin (Knorr) is a drug capable of relieving intense neuralgic pains of functional origin with a completeness which demonstrates that it possesses a very powerful action on the nervous system and through that on the metabolic processes of the body. As an analgesic it is especially active in relieving those pains occurring in paroxysms or which are caused by nerve storms. It proves an active analgesic when pain is due to alterations in the posterior column of the spinal cord, as in the severe lightning pains of locomotor ataxia. "Tabloid" Antipyrin, 2½ grains, sugar-coated, supplied to the medical profession in bottles of 24 and 100 at 8d. and 2s. 1d. per bottle; 5 grain, sugar-coated or plain, in bottles of 24 and 100 at 1s. 1d. and 3s. 11d. per bottle.

FERRIPYRIN.

Ferripyrin is a combination of ferric chloride and antipyrin first suggested as a hæmostatic by Dr. Witkowski, of Carlsruhe, in the THERAPEUTISCHE MONATSCHRIFT, of February, 1895. It is an orange-coloured, readily soluble powder which is absolutely non-irritating and non-destructive to tissues. Investigations as to its practical usefulness confirm the advantages it possesses over ferric chloride. Amongst these may be mentioned its applicability in powder form, its non-corrosive and particularly its simultaneous analgesic action, due to its relation to antipyrin.

Topically Ferripyrin may be applied by means of an insufflator or in solutions of from 1 to 16 per cent. By the mouth the average adult dose is 8 grains, 3- to 5-grain doses being administered to children. It is supplied to the medical profession in 1 oz., 4 oz., 8 oz., and 1 lb. tins, at 2s. 10d. per oz.

The above are produced by the Farbwerke, vorm. Meister, Lucius, and Brüning, Hoechst-am-Main, and specimens may be had, as well as literature bearing on these and other new remedies, upon application to the agents,

BAILLIÈRE, TINDALL, & COX'S NEW BOOKS

Heart Disease; with Special
REFERENCE TO PROGNOSIS AND TREATMENT.

By Sir WM. H. BROADBENT, Bart., M.D., F.R.C.P. Lond., Physician in Ordinary to H.R.H. the Prince of Wales; Physician to St. Mary's Hospital. Price 10s. 6d. [*This day.*

Applied Bacteriology;
A MANUAL FOR STUDENTS AND PRACTITIONERS.

The latest Methods of Research and their application.

By T. H. PEARMAIN & C. G. MOOR, M.A. Cantab., F.C.S. With 81 Illustrations in Colours. Price 12s. 6d. net.

By the same Author (price 3s. 6d.), a resumé of the above,

Aids to Bacteriology.

Röntgen Rays in Medical Work.
A SYSTEMATIC GUIDE TO THE USE OF THE X-RAYS IN MEDICAL AND SURGICAL DIAGNOSIS IN DENTISTRY, AND IN OTHER BRANCHES OF SCIENTIFIC INVESTIGATION.

By DAVID WALSH, M.D. Ed., Physician to the Western Skin Hospital, Honorary Secretary to the London Röntgen Society.

With an Introductory Section dealing with electrical methods, by J. E. GREENHILL.

Illustrated with a large number of photographic plates printed on art paper. Price 6s. net. [*This day.*

Manual of Practical Medical Electricity.
By DAWSON TURNER, B.A., M.D., F.R.C.P., Lecturer of Physics and Electro-Therapeutics, Surgeon's Hall, Edinburgh.

2nd Edit., with chapters on the X-Rays. Price 7s. 6d. [*This day.*

Diseases of the Gall Bladder
AND BILE DUCTS.

By MAYO ROBSON, F.R.C.S., Member of Council and Hunterian Professor, Royal College of Surgeons of England; President of the British Gynæcological Society; Senior Surgeon to the Leeds General Infirmary.

Price 7s. 6d. Profusely Illustrated.

"It would be hard to praise this book more than it deserves, and if anything in surgery could be called final, this title might fairly be given to Mr. Robson's work."—BRITISH MEDICAL JOURNAL.

Chlorosis: The Special Anæmia
OF YOUNG WOMEN, ITS CAUSES, PATHOLOGY, AND TREATMENT.

Being the Report to the Scientific Grants Committee of the British Medical Association. By E. LLOYD JONES, M.D., B.C. Cantab., Pathologist to Addenbrooke's Hospital, Cambridge. Price 2s. 6d. [*This day.*

The Vaginal Radical Operation.
By Professors LEOPOLD & THEODOR LAUDAU of Berlin.

Authorised Translation by B. L. EASTMAN, M.D., Assistant in the Laudau Frauen-Klinik, Berlin, and ARTHUR E. GILES, M.D., B.Sc., M.R.C.P. Lond., F.R.C.S.E., Assistant Surgeon, Chelsea Hospital for Women.

[*With the Original Plates, price 7s. 6d. this day.*

Modern Therapeutics.
By GEORGE H. NAPHEYS, A.M., M.D.

Ninth Edition. Revised, enlarged, and brought up to date by Drs. ALLEN SMITH and AUBREY DAVIS.

Two Vols., bound half morocco.

Vol. I.—General Medicine and Diseases of Children. Price 30s.

Vol. II.—General Surgery, Gynæcology, & Obstetrics. Price 30s.

"Marvellously accurate and complete."—NEW YORK MED. RECORD.

Manual of Physiology.
With over 300 Engravings and Coloured Plates. Second Edition. Price 15s.

By Professor G. NEIL STEWART, M.A. Cantab., M.D., D.Sc.

"It is one of the very best English text-books."—THE LANCET.

"We do not know of one that comes up to the ideal text book as does Professor Stewart's volume."—BRITISH MEDICAL JOURNAL.

Brass's Atlas of Histology.
The most beautiful and artistic medical work ever produced. A magnificent gift or prize book.

66 Coloured Plates with descriptive text. Bound half morocco, gilt edges. Price £1 11s. 6d. net.

"Will have a large sale among teachers and students."—THE LANCET.

"No praise can be too high for the accuracy and beauty of the work."—BRITISH MEDICAL JOURNAL

Clinical Manual of Mental
DISEASES.

By A. CAMPBELL CLARK, M.D., F.F.P.S.G., Mackintosh Lecturer on Psychological Medicine, St. Mungo's College, Glasgow; Medical Superintendent of Lanark County Asylum, Hartwood. Price 10s. 6d.

"Ought to be accepted as the latest and most trustworthy guide to the student, as well as to those who have the responsibility and care of the insane."—THE MEDICAL PRESS.

Gout and Goutiness and their
TREATMENT.

An Address
ON
ETHICS AND INDIVIDUALISM IN MEDICINE.

Delivered at the Opening of the Winter Session of the Queen's Faculty of Medicine, at Mason College, Birmingham, on Oct. 1st, 1897,

BY SIR JAMES CRICHTON-BROWNE, M.D. EDIN., LL.D., F.R.S.,
LORD CHANCELLOR'S VISITOR IN LUNACY.

GENTLEMEN,—This is a day of salutations. We are met here, as are many other groups of men with pursuits or interests like our own in London and the provinces, to greet a new medical year, to welcome those who have come to join our ranks, and to exchange words of encouragement with one another. On such a ceremonial occasion it would not be appropriate, I think, for him who is made a mouth-piece of the hour to indulge in any disquisition on the special professional topics that engage his attention and with which he is no doubt most competent to deal, and least of all would such a course be justifiable when, as happens this evening, the speaker is interested in a very special specialty, recondite in its subject, complicated in its relations, and highly technical in its terms. I shall not, therefore, take advantage of the opportunity to inflict upon you a discourse on mental perturbations, or on the molecular commotions of the brain; nor shall I attempt to elucidate any point in nervous mechanism. I shall merely submit to you a few general observations suggested by my visit to Birmingham, and by the circumstances of this vigorous and flourishing medical school, a new session of which opens to-day. And in the first place, gentlemen, as a disinterested observer having some knowledge of many medical schools and not being personally connected with any one, I would congratulate you who are beginning or continuing your studies here, on the very favourable conditions under which these studies will be carried on. The history of your school is an instructive illustration of the rapid evolution of a useful and necessary institution. The germ of it, as your Calendar says, was planted just seventy-two years ago in a private house, where some classes were conducted by Mr. Sands Cox, but in three years that germ had sprouted into a medical school; in twenty-eight years it had grown so luxuriantly as to be deemed worthy of being fenced about by Royal Charter; and in sixty-seven years, that is to say in 1892, having meanwhile branched out in various directions, it blossomed into its present comeliness, as the Queen's Faculty of Medicine of Mason College. In little more than the allotted term of a man's life, an insignificant private enterprise has developed into a great and prosperous public seminary for medical education, fully organised and thoroughly well equipped in every department. So complete is your school, so adequate is the education it offers, that its students are entitled to ask that facilities should be given to them for the acquirement of degrees, and success must therefore be wished to the project which is now on foot to obtain the authorisation of a Midland University.

The advantages which your school derives from its union with Mason College are so patent and well known to you that I need not even name them; and the advantages which Mason College derives from its union with your school will, I am sure, be generously acknowledged by the representatives of its other faculties. At this very moment every medical student I am addressing must, I believe, experience a stimulus as well as a sense of pride in the knowledge that an alumnus of this college has attained to the distinguished position of Senior Wrangler at Cambridge; while the students in the faculties of arts and science cannot, I am sure, but regard with some sympathetic interest the admirable work in myology and teratology that being done in the anatomical department by Professor Windle, your accomplished and energetic Dean; the valuable researches into the functions of the suprarenal bodies that have been undertaken by Dr. Vincent; the original pathological observations that we owe to Professors Saundby and Barling; the ophthalmic studies of Mr. Priestley Smith; and the surgical achievements of Mr. Jordan Lloyd. It would be trite to discuss the actions and reactions of Mason College and the Queen's Faculty of Medicine upon each other, but I may perhaps be permitted to say a word as to the influence which seems to have been exerted on both by their surroundings. Institutions, colleges, schools, societies, have their distinctive characters, just as have individual men and women; and the distinctive character of Mason College and the Queen's Faculty of Medicine is, I should say, practical and utilitarian. The active, searching, contriving, empirical spirit of Birmingham has called both of them into being to meet urgent public wants, and has impressed its stamp upon them. The Founder of Mason College was undoubtedly moved to establish it by recollections of the difficulties he himself experienced in preparing for an industrial career, and by a desire to promote the manufactures of the town and district, and the original deed provided for scientific instruction only, with the addition of modern languages, which of course have a commercial value. The founders of the medical school, on the other hand, aimed at the education not of professors or devotees of science, but of expert surgeons and medical men qualified to practise their art. Both the college and the school have in recent years greatly enlarged the scope of their teaching, letters on the one hand and science on the other now taking a much more prominent place than they once did, but both are still dominated by a regard for the immediate economical requirements of the place and period.

The practical and utilitarian intent which I have ascribed to this college and school will no doubt be regarded by some as an opprobrium. We have it often dinned into us that it is knowledge "for its own sake" which we should pursue, without any concern as to its applications, but while not disputing this authoritative dictum I would suggest that there is room for all kinds of knowledge in this world, and that while knowledge for its own sake is good and may unquestionably lead to unforeseen results of the utmost value, knowledge for bread-and butter's sake is not bad, and must always have a primary claim in beings who have the pangs of hunger to appease. Pure science, erudite learning, and proud philosophy find, perhaps, their fittest homes in colleges and schools to some extent sequestered and remote from the busy haunts of men, while technics and science bearing on industry and the business of life will be most suitably located in great centres of population like Birmingham. Carlyle called Naseby field the navel of England, and Birmingham might perhaps be described as the medulla oblongata of the industrial world, made up as it is of a collocation of centres that are essential to the maintenance of crafts and manufactures in all quarters of the globe. Without the weapons, the implements, the machines, the fabrics that it pours forth, human activities would be paralysed in many regions, and any interruption of its functions would certainly have an asphyxiating effect upon the whole of this country. The atmosphere of Birmingham is keenly practical, and it is but natural that the institutions of Birmingham should have a practical complexion.

As regards the medical school here, the practical turn given to its teaching in harmony with the *genius loci* is worthy of all commendation. Its main purpose is not to fit out original investigators, but to arm and discipline those who are to contend with the forces of disease; and in order to do that it has, as science progresses, to insist more and more on laboratory, dissecting room, and clinical work. It is steadily increasing its laboratory accommodation, and you do not require to be urged to avail yourselves of the opportunities thus opened out to you. Nay, it occurs to me that a word of warning of an opposite kind may be useful, and that you should be recommended, in your addiction to laboratory work, not to under-estimate the utility of the systematic teachings of your professors. Lectures do not certainly play the prominent part in medical education that they did in my student days. In the University of Edinburgh thirty years ago we had to listen to lectures five hours a day five days a week. But while admitting that lectures were formerly overdone, while practical, experimental, and tutorial work was neglected, I cannot agree with those who would discard them altogether from our curriculum as mere slipshod versions of what is to be found in the text-books, or who depreciate their teaching power. The spoken word has a vitalising influence that is all its own, and oral instruction has physiological claims to the academic precedence which has been at all times accorded to it. In this bookish age a very large proportion

Digitized by Google

of our acquired knowledge comes to us through the eye, whereas in bygone centuries the ear was the main, nay, the almost exclusive, channel for the importation of learning; and there can be no question that the invention of printing has to some extent modified the structure of the brain by diminishing the functional demands on its auditory paths and rendezvous. The increased use of one sensory centre and the diminished use of another, in connexion with cerebral activities of wide range and potency, must, during the development of the cortex and brain generally, have led to changes and deviations in the associative paths and internal convolutions linking and lying between the sensory and the motor centres. And thus traffic of a certain class having been diverted from the ear to the eye there must have been a broadening and multiplication of the high-roads and bye-ways leading from the visual centre in the occipital lobe to the central or distributive and the efferent or expressive centres, and a corresponding narrowing or abandonment of the routes connecting the aural centre in the superior temporo-sphenoidal convolution with them. Vision has become more and more the dominant sense in education. But although vision is the dominant sense, we must not rely upon it too exclusively, for even our simplest ideas are built up by contributions from all the senses, and those mental stores are most useful and available that can be readily approached by several different alleys. Entire dependence on a single avenue of sense may give very precise reactions graded in accordance with the intensity of one kind of stimulus, but the full and free growth of intelligence requires the well-balanced activity of all the organs of sense by which materials for distinction and comparison are supplied. All the secondary sensations that fringe our mental images enhance their working value and enable us to lay hold of them more readily, and the most perfect response is obtained from those cerebral centres that are invaded by sensory impulses of several different sorts. Clearness of conception, quickness of apprehension, and breadth of thought belong to the brain that has been thoroughly opened up, both in its auditory and visual tracts and their connexions, and hence the high significance of ear-teaching in education. There is sagacity in the Prayer-book exhortation to god-parents, that they are to call upon those for whom they are sureties "to hear sermons," and I am inclined to believe that the dialectic and polemical ability of my countrymen in Scotland is to be attributed in some measure to the voluminous pulpit utterances to which they had to listen in their boyhood.

I am not suggesting, however, gentlemen, that there will be anything of the nature of the sermon in the lectures that you will have to listen to in this college, and that will, as auditory impulses, after passing through masses of nerve fibres and throngs of cells, enter and illuminate your consciousness. Sound these lectures will be I have no doubt, cogent in argument, elevating in tone, but they will not be homiletical in character, but will necessarily deal with those direct observations and material problems and experiments that form the foundations of medical science and that have taken the place of the dogmas and speculations upon which it once mainly rested. All recent progress in medicine has depended on research and discovery carried on by physical and chemical methods. The mechanical principles that were first applied in anatomy, the mother science of medicine, to the explanation of the construction and movements of bones and muscles have been carried by the physiologist into every organ of the body and into the arcana of the tissues, and have been shown to be essential to the understanding of the changes that take place in them during the performance of their functions. And at the same time the aid of chemistry and electricity has been invoked to drive back step by step, and if possible to banish altogether, that vitalism which was at one time all but supreme in the domain of animal physiology. And now, not content with his corporeal conquests, the physiologist is pushing his mechanical methods into the realm of psychology, and is seeking by means of them to investigate the data of consciousness. Having by electrical stimulation and other experimental procedures localised sensory and motor centres in the brain, having shown that there is a definite order of development in the nerve tracts, and having disentangled to a large extent the paths of nervous impulses of various kinds, their halting points and goals in nerve cells, he is now eager to catch ideas on the wing and to examine them in the usual manner. Helmholtz, in his great works on vision and hearing, was the first to show how physics mount into physiology and psychology, and after him Weber, Fechner, Lotze, and Wundt have step by step pushed forward the parallels of the material accompaniments of thoughts and feelings. And quite recently a movement has sprung up in Germany to advance still further mechanical explanation of the facts of mental life, and to bring psychology, which has always been scientific in as far as it has observed and classified and analysed phenomena, into line with the exact sciences of external nature. Experimental psychology has been inaugurated, and research laboratories, in which the physical and vital changes that are associated with mental processes are to be measured and tested, have been established. Originating in Leipzig, experimental psychology has taken root in several other centres on the continent, has spread to America, where it has been eagerly adopted, and has at last made its way into England. The University of Cambridge has voted a sum of money to be devoted to investigations in connexion with it, and a few months ago a meeting was held in London to promote the establishment of a laboratory for its study in University College. The names of those who attended that meeting are a sufficient guarantee that the project which it approved will be successfully carried out. I have little doubt that suitable arrangements will be made for instruction in the new methods of psycho-physical research in University College, and that in course of time other schools and colleges—Mason College amongst them—will follow its example and afford facilities for studies in anthropometeric psychology. I have little doubt, too, that such studies will be fruitful of useful results, by widening the scientific basis of psychology and supplying us with standards by which to gauge the speed and duration of certain neural operations, the variations in these in different individuals, and the depth of certain mental defects. But at the same time I am disposed to think that exaggerated notions are entertained as to what experimental psychology can actually accomplish. Its field is, after all, a narrow one. It can never supplant self-observation and introspection as means of mental analysis, and must indeed always to a large extent lean on these. It is practically restricted to the measurement of sensations and movements and the gaps between them, or the simplest mental processes; and hitherto it has, it must be admitted, been somewhat ambiguous and indefinite in its declarations. For my own part I look with more sanguine expectations of light on the obscure problems of mind to comparative, ethnical, developmental, and pathological psychology—which may all, of course, be investigated by experimental methods—than to the new experimental psychology strictly so-called.

We all gratefully acknowledge the immense debt we owe to experimental physiology with its exact mechanical methods. It has dispelled myths and errors, supplied us with a body of precise and well-organised knowledge, and revolutionised our treatment of disease; and it promises in the future not only to augment our healing power, but to afford trustworthy guidance in education and in the regulation of some social relations. As it stands to-day physiology, it seems to me, offers a liberal culture to all who study it. An independent science itself, but in touch with all other sciences, it brings into exercise observation, judgment, and memory, while it passes in review questions of surpassing interest to every human being, and thus confers an admirable intellectual discipline while storing the mind with information that must prove useful in the conduct of life. I would be disposed to say that physiology might henceforth with excellent results enter much more largely than it has hitherto done into a general liberal education; that is to say, into the education of those who do not intend to follow medicine as a profession; and I would even suggest that the young men of Birmingham who are destined to carry on its staple trades might be worse employed than in attending a course of physiology in this college. I read the other day that the late Sir Isaac Holden attributed his invention of the square-motion wool-combing machine, which made his fortune and brought about a complete transformation in our woollen industries, to the fact that he tried to imitate as closely as possibly the movements of the hand of the hand-comber. On this physiological basis he laboured consistently, and on it he achieved success where many others had failed. And the human body, you may depend upon it, is a rich storehouse of practical hints of this kind—a storehouse of which physiology holds the key. It is an epitome of mechanics, and in its exquisite machinery the engineer, the artificer, and the

Digitized by Google

inventor may still find, perchance, some vein of new inspiration. But apart from any such possible treasure trove, the study of physiology is well deserving of the attention of those who are to engage in arts and manufactures like those of Birmingham, for they will derive from it habits of thought, special insight, broad views and sympathies which cannot fail to be useful to them as producers themselves, or the superintendents of those who produce. But, whatever outsiders may think of it, there does not seem much danger that the study of physiology will be too lightly regarded by the medical student in these days. Its definiteness and lucidity appeal with special force to him, and its mechanical methods take possession of his mind at a very plastic age; and, indeed, the risk would seem to be that physiology, in conjunction with anatomy and pathology, may materialise his conceptions, bind him down to a purely mechanical interpretation of the universe, and so cause him to lose sight of truths which are not less valuable than physiological principles to the medical man. It is expedient that from time to time the medical student should be induced to raise his eyes from the test-tube, the microscope, or the galvanometer, and to fix them on a wider horizon; and, mindful of this expediency, I would ask you to allow me in what I have further to say this evening to point out to you that man, after all, stands above physiology, and that there is that in his nature which mechanical methods can never enable us to reach or appraise.

The revelations of comparative anatomy and the brilliant discoveries that we owe to experiments on animals have assuredly inclined us to take an animal view of human nature. Every tissue that enters into the composition of man's body has its analogue in the bodies of creatures far beneath him in the scale of being. Every organ with which he is endowed is seen in greater or less elaboration and completeness in the beasts that perish. Every function he exhibits is displayed in a rudimentary or fully evolved state by inferior organisms. And yet, notwithstanding all homologies and resemblances, there is a great gulf fixed between human and animal nature. Man, the breviary of all bygone evolution, stands pre-eminent in form, structure, intelligence, and, above all, in the possession of a moral sense. In his power of assuming the erect attitude and of extending and fixing the hip- and knee-joint when standing, in the development of his hands into instruments of prehension, and in the freedom of movement of his upper limbs, in the perfect poise of his head on the summit of the spinal column, in the high degree of sentiency conferred on him by his exposed integument, in the modelling and mobility of his face as an instrument of expression, man presents characteristics that are entirely his own. And in a still higher degree is he differentiated from any animal by the mass and structure of his brain, which (although exceeded in absolute weight by the comparatively simple brains of the elephant and whale, whose huge body mass demands large sensory and motor centres) is, in his civilised state, more than three times the weight of brain of the highest anthropoid ape—the animal that most closely approximates to him—from which again it is even more widely separated by the proportional development of its parts, by the complexity of its cortical structure, and by its richness in association centres. But it is by what are incorrectly spoken of as the functions of the brain, by his mental faculties, his reason and intelligence, that man is distinguished from animals far more than by visible cerebral differences. I say these are incorrectly spoken of as the functions of the brain, for they certainly cannot hold the same relation to that organ that movement does to the muscles or bile to the liver. The brain is a sensori-motor machine, concerned with the storage and liberation of energy, and it is contrary to the principle of the conservation of energy that will, or emotion, or ideas, which are immaterial agencies, should interfere with movements in nervous arrangements and disturb the balance between work done and the diminution of the intrinsic energy of the body and its contents. Nothing can be derived from motion but another motion, nothing from mental process but another mental process; and thus the facts of consciousness can never be explained by molecular changes in the brain, and all that we can do is to fall back on an hypothesis of psychophysical parallelism which assumes concomitant variations in brain and mind. There is a physical universe of which only a fragment is known to us. There is a psychical universe in a corner of which we live, and move, and have our being. We may picture these to ourselves as circles which impinge on each other at the first moment of conscious existence, which intersect more and more as life goes on, their largest intersection (including but a small segment of each) being reached when life is at its full, and which then withdraw from each other as old age sets in, and part company at death. But whatever image we may adopt, we must hold fast to the truth that mind and matter are distinct essences, irreconcilable in their nature, though mysteriously accordant in their operations; that only in the elementary processes of mind made up of sensory and motor elements has correspondence with physical changes in the brain been traced out; and that we are still without any cerebral explanation of those higher powers of mind which exalt man above the animal creation.

Without attempting even to sketch the intellectual and emotional characteristics which place human nature on a pedestal above all other nature, I would direct your attention specially to that moral sense to which I have already referred as a peculiarly human attribute, and which, as Professor Huxley has insisted, is not derived from the struggle for existence, but implies a reversal of the action that avails in that struggle. In his capacity as an animal man has achieved his success in the world by his superiority in certain qualities which he shares with the tiger and the ape; by his cunning, his power of imitation, his greed, his rapacity, cruelty, and self-assertion; but in his capacity as a social animal he has advanced from savagery to civilisation by the suppression of these qualities and the substitution for them of others of a very different kind—qualities such as sympathy, self-restraint, justice, and benevolence, of which we have no hint in any level lower than his own. In his advance into manhood he has created for himself an artificial, a social, an ethical atmosphere which he alone of living beings breathes. In his progress in civilised polity he has prepared for his species an ethical environment which powerfully modifies its characteristics and tendencies, and is in turn modified by it. In that environment what we call goodness or virtue is the potent force, and the survival of the fittest becomes the survival of the best—the survival, that is to say, of those best adapted not to material but to moral conditions of existence. A new standard has been set up. Better and worse mean no longer more or less adaptation to geographical surroundings for the time being, but more or less conformity to laws, rules, precepts, and sentiments of artificial origin and of everlasting obligation. Now, if we allow that certain rudimentary virtues, such as temperance or moderation in the indulgence of appetite and industry, may be of advantage to the individual and the race in the competition for life, it must still be maintained that morality proper only emerges when altruism, sympathy, or a desire for the happiness of others appears on the scene, and that in morality proper an entirely new principle is involved. Even if we allow that the moral sentiments, like other natural phenomena, have been reached by a process of evolution, we must still bear in mind that the immoral sentiments must have had the same origin, and that our preference for the one over the other can be found only in human intuition and experience. Moral sanction has not grown out of environment or outer relations or circumstances, but out of an element in human nature, the accumulated influences of individual men, and the initiative of certain great men who have from time to emerged from the mass of mankind and become active agents in differentiating the ethical environment around them and in all time coming. Everywhere in human history we discern not only the slow accretion of morality by the impalpable additions made to it by submerged millions, but its sudden upheaval from time to time by the workings of the spontaneous impulses of great men whose names stand for ever prominent.

This immensely energetic quality, greatness, genius, or heroism, to which so important a part is assigned, is a peculiarity, a departure from common form, and we must carefully distinguish between the causes which produce it and the causes which tend to preserve it. It is not an adaptive modification. It may be fostered, pinched, or blighted by environment, it is not produced by it. Its origin is to be sought in those internal molecular changes which give rise to variations. It is a divergence from the parent type due to influences operating upon the ovum and the embryo, and is independent of external conditions, physical or social. Neither in descent nor in personal vicissitudes is any adequate explanation of it to be discovered. The motherly theory of greatness, which only removes the difficulty one

Digitized by Google

generation, does not bear examination in detail, for it can be shown that some great men had inferior mothers, and that those of them who had superior mothers differed from them just in those properties that made up their greatness; and the climatic theory is equally untenable, for greatness has not been tied down to any special meteorological conditions, but has appeared in all parts of the planet suitable for the habitation of the best human breeds. It is a sport, a new departure, what we call a spontaneous because an inexplicable variation—inexplicable at least by the biological causes which lie nearest at hand and which we commonly invoke. In every series of living beings that we contemplate, we are accustomed to look for the transition from term to term, by minute and insensible differences, or continuous variation; but we must not shut our eyes to the truth that in such series there are to be noted breaks, or gaps, filled by no transitional forms, but leapt, as it were, by discontinuous variation. Breaches of continuity undoubtedly occur in the evolution of living beings and of particular organs and instincts, and the recognition of such breaches and abrupt or transilient variations, as Mr. Galton has called them, removes a stumbling-block in the way of the acceptance of the evolutionary theory. There are in the animal kingdom many mechanisms and devices useful to their possessors in a state of perfection which while only partially developed must have been not only useless but disadvantageous encumbrances. Now it is clear that with reference to such structures natural selection could have afforded no protection during their imperfect and preparatory stages while they were advancing by minimal steps, and that we can only account for them by supposing that they appeared at once, fully formed by a volt of discontinuous variation. Environment is continuous and varies merely in degree, but species and organs are discontinuous and differ in kind; and it is difficult to understand how the former can be the cause of the latter. In studying discontinuity, realising that the missing links are infinitely more numerous than the existing ones, we begin to suspect that the chain of being may resolve itself into a series of rings disconnected but still somehow related, as evidenced by their form, size, proportion, substance and arrangement.

In plant life we have many illustrations of variation due to environment which disappear when the environment is changed, as, for instance, in the alterations which present themselves in marsh plants grown on dry land, and in lowland plants grown on chalk downs or mountains, and of spontaneous variations due to a deeper cause and unaffected by changes in environment, as, for instance, in the copper beech, an unaccountable sport from a green beech in a German forest which retains its coppery hue in the most widely different soils and climates, and the weeping habit in the elm and ash, a novel trait without environmental justification which is perpetuated under diverse circumstances. What in environment or in immediate ancestral conditions have we to thank for the double rose or Williams pear or Japanese chrysanthemum? It is all very well hypothetically to ascribe such variations to over-nutrition or under-nutrition or to say that variations group themselves in the probability curve, but the facts remain that certain individuals have stepped out of the parental type while innumerable other individuals also over- or under-nourished have proved true to it, that variable plants never cease to vary, that similar variations occur under dissimilar conditions, and that dissimilar variations arise under conditions nearly uniform.

In the animal kingdom variations of all kinds are abundant and multiform, some of them obviously due to surrounding conditions and some, as far as can be ascertained, not so; some built up by gradual, almost impalpable, increments, and some presenting all at once a large degree of originality. Our canine friends are a highly varied group, probably descended from several wild species, and amongst them we observe slight modifications due to habitat and selection of variations which can be traced up in diminishing proportion through a line of ancestry. With such variations we are familiar, but the sudden appearance of an Albino in a dark-haired family is a somewhat startling phenomenon, which apprises us, as Huxley said, that "nature is often brusque and makes leaps and bounds." Of this sort of advance examples are afforded by the hairy moor-hen, in which the feathers are, for no conceivable reason, destitute of barbules; by the Angoras amongst domestic animals—the goat, the cat, and the rabbit—in which the hair is long and silky; and by the "rhinoceros mice" found at Taplow, which were entirely naked and without hair except a few dark coloured whiskers. These variations were certainly not due to selection or environment any more than are those which we see daily in the human families of our acquaintance, in which a number of children born of the same parents and reared in practically identical conditions differ from each other in a remarkable manner in size, build, colour and mental capacity—in which, perhaps, an idiot and a monster (and we must remember that, as St. Hilaire taught, there is order in abnormality) are growing up side by side with a genius and a beauty.

As regards vegetable and animal variations alike—and among the latter we must include the great man—there are, it must be admitted, a large number for which no exciting cause can be discovered, and which must therefore be classified, provisionally at any rate, as spontaneous or accidental. Discontinuity in variation, of which species may be a standing monument, is not certainly in the environment; so we are bound to look for it in the living thing. And in this connexion it is well to remember Darwin's remark, that as regards variation the nature of the organism is far more important than the nature of the conditions. Those variations referable to the living being Darwin in the first instance described as due to chance, an incorrect statement, as he allowed, merely intended to cover ignorance; and to-day we are still obliged to speak of them as fortuitous. Taking the universe in its entirety, regarding all as "parts of one stupendous whole," such variations are included in the unity of the cosmos. But the cosmos is a wide word, and there is no inconsistency in holding that variations, although summed up in the nature of things, are not interpreted in the organic nature by which they are immediately surrounded. No doubt in a strict sense the great man is the product of his antecedents, but these antecedents in the absence of the great man himself could not have afforded any clue to his personality. Causes become apparent in their effects; and the great man being not a simple mechanical phenomenon, but a complicated problem of conscious life, is not to be explained by a reference to elements of a different order containing no trace of his characteristics. The combination of these elements in such a manner as to produce this particular result has to be explained, and that can only be done by taking into account the result itself. All ultimate explanation must look to the end and read back the nature of the particular result into the remotest antecedent. It must concern itself with the whole evolution, and rest on proof that there is an organic unity binding the whole process into one and making it intelligible; that there is evolution and not merely gratuitous metamorphosis. But of remote causes of this description science in its still purblind state does not take cognisance, and we need not, therefore, be surprised to find the most recent authority in this department, Mr. Bateson, whose compendious researches are a rich dower to science, dismissing the subject in these words: "Inquiry into the causes of variation is as yet in my judgment premature."

It is clear that variations, the cause of which are as yet inscrutable and beyond investigation, may still be conveniently spoken of as spontaneous, and the great bulk of variations fall under this description, while as regards these variations which, it is alleged, can be traced to diversified external conditions, to food supply, climate, use and disuse, pressure, &c., there still remains to be taken into account, when allowance has been made for all these, the power to vary, and to vary in such a manner that the symmetry and general balance of the organism are maintained. We are obliged to fall back upon a law of reproduction, involving, not only resemblance to parents, but individual difference from them; upon covert causes infinitely remote, setting up a tendency to vary as well as to repeat; upon a duplicity of the original vital impulse, whensoever derived, operating upon the totality of living beings from the commencement. And if we accept this view, and regard spontaneous variation as one of the fountains from which have sprung those beneficial differences which natural selection has adopted and accumulated, and if we connect it with established facts as to the order in which animal forms, and more especially vertebrates, have appeared in the long history of the fossiliferous crust of the globe in definite sequence, beginning with the lowest and culminating in man, we come to see something of "an increasing purpose" running through the ages. We may come even to acknowledge that evolution is a continuous revelation and variation a perpetual miracle. "The flowers," said Carlyle,

Digitized by Google

"are eyes looking out upon us from an inner sea of beauty." May not the great man be a flash of illumination from an unsearchable firmament of wisdom?

But whatever his origin, the great man is an indisputable fact recurring with greater or less frequency. A wonderful complex of higher faculties not attributable to inheritance from either parent, or from any more remote ancestor, or to the play of investing forces or events, he comes with peculiarities which distinguish him from the average man and enable him to re-model the average man more or less extensively and powerfully. Selected by his environment, and moulded and biased by it in some degree in his plastic youth, he does not owe to it his essential qualities.

How little the genesis of the great man depends on his personal environment may almost, I think, be inferred from the histology of the brain. At the sixth month of fœtal life the cortical substance of the cerebrum contains neuroblasts equal in number to the cells present in it in its most mature state, that number being computed at 1200 millions. True, an enormous elaboration of structure subsequently takes place. The neuroblasts grow in size and change in shape, become nucleated and nucleolated nerve cells in which pigment is deposited. The cytoplasm of these nerve cells changes in chemical constitution, as shown by its reactions to staining agents. The cells undergo polarisation, and the neurons and then the dendrons are sent out. The medullation of different nerve fibres at different rates takes place, and there is a multiplication of tangential nerve fibres. The brain goes on expanding and becomes more complicated up till adult life, but whenever the number of its cells is determined its groundwork may be said to have been laid down and its ultimate plan to have been outlined. Now genius or greatness is unquestionably involved in the ground plan and elevation of the brain, and when it appears, therefore, it must have been potentially present at the sixth month of existence, when the muster of neuroblasts is complete; but up to the sixth month of existence the environment is uterine and of a singularly uniform description, affording no conditions equal to the differentiation of the genius from the average man.

In primitive times a great man born into any tribe or clan must have been to it just what a new and advantageous structural variation is to an animal. His greatness, courage, ingenuity, insight, and energy must have helped it in its tribal conflicts and conduced to its survival. And although, taking the tribe as a vital unit, the greatness of the great man could not be perpetuated as advantageous structural modifications are, yet might it be very far-reaching and, indeed, permanent in its effects. The example of the great man would be imitated by members of the tribe who were not great, a process which we see in operation to some extent amongst animals of gregarious habits, and his greatness would live in the traditions of the tribe and, in a manner exclusively human, influence the conduct of unborn generations, and thus determine at many critical epochs their tribal development. And in times not primitive the influence of the great man becomes more and more apparent. History is indeed a record of its interactions with the existing temperament, prejudices, and ideals of a people in certain physical conditions. In every individual life there are decisive moments when a choice has to be exercised that determines the whole future course of its current, and in every nation's life there have arisen decisive men who, by precipitating war or revolution or reform, or by their inventions, discoveries, or ideas, have irrevocably changed its career, have become factors in its environment, and deflected its advance. Would the United States of America have been what they are to-day had Columbus and Washington never lived? Would Europe be mapped out exactly as it is had Napoleon never aspired? Does not Italy owe its unity to Cavour and Garibaldi, and Germany its empire to Bismarck and Moltke? Can we believe that our insular position would have given us the sea power we possess had men like Drake, Hawkins, Frobisher, Blake, and Nelson never grown up on our shores? Have not men like Frederick the Great and Cromwell determined great changes in national life? Have we not seen nations stagnating for want of great men and bursting into vigorous efflorescence when a group of them appeared? Is it possible to believe that the differences between one nation and another, whether in intellect commerce, arts, or morals, depend simply and solely upon physical circumstances or geographical position? Can we credit it that, had the original stock of our English people been planted in the malarious forests of Benin, their descendants would have been to-day black, bloodthirsty, and treacherous savages, rejoicing in Ju-Ju, and that the late subjects of King Drunami, had their progenitors been located here, would have been now a wealthy, humane, and prosperous white people? Surely we must keep in mind the vastly preponderating influence of racial constitution and the manner in which this is differentiated from within as well as from without. We see nations stimulated and biased in every direction by their own offspring, and bearing indelible traces of the great men who have sprung up within their borders, and who have often exerted an influence far beyond national barriers. There is no Englishman to-day who does not in his thoughts or conversation bear the impress of him who sleeps at Stratford-on-Avon, who came like a meteor, but has stayed like a sun, the only genius who ever made universality a success. Scotland still stiffens with the fierce rigidity of Knox, and melts into tenderness at the songs of Burns. To say nothing of the founders of religions, men like Luther and Loyola have swayed mankind under the most diverse geographical conditions. Mr. Herbert Spencer is himself a conspicuous refutation of his own theory, for the influence of his truly original intellect, the making of which is not to be recognised either in the long story of the race or in the social state into which he was born, has proved a leaven in science, has permeated into the general thought of the time, and permanently affected social relations. So, too, Darwin has brought about an unexpected and radical change in intellectual government and created a critical epoch in science—a period of rapid evolution after an interval of quiescence. Would it not be correct to say that Arnold by his religious idealism has transmogrified the higher education in England? Hours might be spent in enumerating and defining the specific influences that great men have exerted on national evolution—men like Julius Cæsar and Marcus Aurelius, Charlemagne and Hildebrand, Raphael and Michael Angelo, Milton and Goethe, Voltaire and Rousseau, Gibbon and Hume, Bacon and Newton, Comte and Mill, Davy and Faraday, Ruskin and Carlyle, Watt and Stephenson. I shall content myself with one illustration near home, and I am sure I shall not transgress the rule laid down by the founder of this College, and worthy of all acceptation, that politics are not to be referred to in its precincts, if I say that we could all name a great name, a living statesman, an unmistakable product of Birmingham, who has transcended his antecedents, and by virtue of his individual endowments has improved the environment for all who live in his native city, has quickened our national life, and, setting at nought geographical restrictions, done something to consolidate a world-wide empire.

In the history of medicine every chapter might have as its heading the name of a great surgeon or physician. In the biographies of Linacre, Sydenham, Harvey, and Jenner distinctive steps in advance may be measured and connected with personal initiative; and in every branch of medicine and surgery as they are to-day, excellent though the work accomplished by the rank and file may have been, a few great pioneers have determined and guided progress. In my own department, neurology, it is certain that progress has hinged on the genius and labours of a few great men—Charles Bell, Marshall Hall, Claude Bernard, Brown-Séquard, and Hughlings Jackson; and I cannot conceive that it would have been in the forward position in which it is had anyone of these been missed out. Neither can I conceive that had any one of them failed to appear, some understudy or *alter ego* would have been supplied by the geographical and social conditions of the period to fill his place. At this hour we have amongst us in the circle of our profession a brilliant example of the great man who changes for ever the environment in which he finds himself. It will not be gainsaid that Lord Lister has once for all and profoundly influenced the practice of surgery and medicine. Without a forerunner except Pasteur, by methods strikingly novel, in the strength of a fresh variety of intellectual power, he has reached discoveries which have already given check to the cosmic process in certain directions, and which must ultimately benefit the whole human race.

We have spoken of the influence of greatness in the creation of environment, but we must not overlook the less conspicuous but more widely diffused influence of men who are not great but still possess individual initiative. Every man may be a great man in a small way, and leave his social environment better or worse than he found it. The arc-light, like genius, lifted aloft, scatters its radiance afar, and, like genius, is apt to flicker and splutter in doing so; but the

Digitized by Google

glow-lamp, like the patient drudge, in its lower and narrower sphere, emits a useful and a steadier light, one glow-lamp differing from another in glory. And so each average man may not only fill his average place, but, by virtue of his little individual talent, do something to increase or diminish the momentum of the social movements that are going on around him and bring about, no matter on how small a scale, a re-casting of social relations. For each man is a variation, even if only in an infinitesimal degree, from all the men who have preceded him The zoological man in him is a settled affair, but the human constituent is still in a state of flux, and it is for the new combinations that it effects that we are constantly watching with such intense interest. Variations are, as we know, more frequent under domestication than in a state of nature, and have a far wider range in the civilised than in barbarous races of mankind. In the faces of our own country people we see far greater anatomical differences, a far richer play of expression, than is to be observed amongst negroes; and as regards some of the lower types of our species, it would almost take a shepherd with his eye trained in ovine physiognomy to distinguish one man from another. But the face is a screen on which are projected the dioramic—I might say the cinematographic—changes of the brain within, and it is the brain that is the great theatre of human variations in these days. Without referring to its intimate structure we can see in the fissuration of its surface that it has in every individual a personal identity of its own, while in the products which accompany its functional activity we find idiosyncratic differences, in every case. Sensations, ideas, emotions, active tendencies are the flora and fauna of the brain, and these, while subject in the main as regards their general character, their form, order, and associations, to the influence of heredity and environment, are yet constantly exhibiting new growths and features, random and discontinuous variations. We have amongst them many familiar types, but we have also startling novelties, hideous monstrosities, and beautiful and useful developments. And in this flora and fauna of the brain selection is ceaselessly at work—environmental selection—the climate for them is made up of emanations from other brains and what may be termed artificial or deliberative selections, which I wish to emphasize as the basis of that mental discipline which is so essential to all ethical life. We can within limits regulate our own brain crop. We can weed it and fertilise it, and we can do this by an exercise of that voluntary power which is our proudest attribute. Thousands of ideas shoot up in the mind for one that survives and becomes operative, and the one that survives does so because it is selected by the will. The real force of ideas, said Fichte, is not in the ideas, but in the will of the person who selects them as his.

I do not forget, of course, that the very existence of this will, for which I am claiming such autocratic power, is more and more ingeniously disputed as mechanical physiology advances; and you will, I am sure, be relieved when I tell you that I do not here propose to embark on another Arctic expedition or balloon voyage into the murky polar regions of determinism and free will. But as a practical physician I would just say that I look upon free will as as much a need of the individual and of the race as is fresh air, and that I should regard as a pestilential calamity any widespread abandonment of a belief in it. A sporadic case here and there does not much matter, but anything like a general lapse into downright predestinarianism must mean the extinction of ethics and a reversion to that cosmic process out of which we have with so much pain and effort worked our way. This argument—the argument *in terrorem* founded on the supposed consequences of a doctrine—is no doubt open to objection, but it is more so in relation to secondary and derivative beliefs than to those that are primary and fundamental. Mr. Balfour has made effective use of it in relation to Naturalism, and an appalling picture might be drawn of the results of universal determinism. The illustrations which we possess of its partial ascendancy in Mohammedan races—I say partial, for fatalism is never thoroughgoing—are sufficiently forbidding; and it may perhaps be a sufficient condemnation of it on the present occasion if I point out that its complete triumph would involve the disappearance of medicine as an art. It will be well for you during your curriculum to be on your guard against insidious suggestions of wholesale automatism, for there can be little doubt that the study of reflex action, investigated as it almost invariably is from below upwards, and not from above downwards, predisposes to that faith—an enervating faith—which reduces man to a mere pith-ball in the jet of the fountain of events, helplessly tossed aloft, heedlessly falling, ceaselessly moving, as if animated, and yet the mere plaything of external forces. Apart from all the mystifications of logic and clarifications of science we have just as good evidence for the freedom of the will as we have for our own existence. You will feel and know, when you come to think of it, that you are not, as Münsterburg would have you believe, a mere sequence of ideas, but have the choice amongst these, and that you are bound to exercise that choice in such a manner as to make your calling and election sure—utilising your gifts, recognising your responsibilities, taking advantage of your variations, and being responsive to your environment, thus fitting the place in which you find yourselves. Hold fast to the importance of the individual. Do not worry yourselves about the insignificance and evanescence of man.

You are here in an animal world and an ethical society; you are variations (each of you is a variation), the outcome either of ancestral conditions or of an inherent vital impulse; and you have been selected, you have not been found unfit for survival and condemned to perish. You have escaped the perils of the embryo, of gestation, and parturition; you have fought your way through the legions of pathogenic bacteria that lie in wait for infancy and childhood; you have survived the breakneck hazards of boyhood, and even football has not put an end to you; you have not as yet been devoured by the examination beast of prey; you have proved yourselves adapted to the climatic conditions in which you find yourselves, and have been able to provide yourselves with ample nourishment; you have struggled up into existence so far, and have shown that with individual traits in every case you are all more or less adapted to your environment. And now, selected, vaccinated, educated, you are about to enter upon an entirely new environment as students of medicine, an environment which will again select and sort you, and perhaps in a few instances—I trust a very few—reject you altogether; and which will at the same time remodel those of you whom it selects, and prepare you for still another and more trying environment which you will enter when you go forth from this College as practitioners of medicine. And in that environment by which you are now encompassed, and still more in that larger environment that looms before you, you will, I predict, discover that harmony with your surroundings and happiness for yourselves are promoted by keeping constantly in view the ethical nature of man, on which I have this evening insisted. For you the era of the "ape and the tiger," of tooth and claw, is past and gone. The instincts and promptings that were uppermost in that epoch, its selfishness, cruelty, ferocity, and destructiveness, are still to be seen at work in the human struggle for existence on every hand, and still assert themselves with greater or less vehemence from time to time in every human breast; but in civilised beings they are dominated and held in check, as we have seen, by a new principle that has intruded into human life, the ethical principle creating a sense of duty and enjoining goodness and virtue. And this ethical principle or categorical imperative of duty, as Kant called it, or conscience once awakened in a man can never slumber again, but if neglected or violated becomes itself the source of pangs worse than those which are attendant on the natural order of things. For your own advancement and happiness in life you cannot too soon cease to make an idol of the natural man, for the profession you have chosen is the outcome of quite another cult. It is the highest expression of the humanising process, as opposed to the cosmic process, and its great aim is to assuage the sufferings and heal the wounds of those who have been worsted and trodden down in the struggle for existence, and to mitigate the asperity of that struggle. In the cosmic process pure and simple the medical man is a troublesome meddler, promoting the survival of the unfittest, and protracting the miseries of the condemned. At a recent meeting of the Medico-Legal Society of New York, it was gravely argued that suicide is, under certain circumstances, to be professionally recommended, and that in cases of incurable, fatal and agonising disease the physician should be empowered to terminate life by what is designated "homicidal euthanasia." If you would justify your professional existence to yourselves, you must early put aside such extravagances and attune your ears to those ethical harmonies which mingle with the fierce discords of

Digitized by Google

the fight, and which happily grow more and more audible as time rolls on.

I admit that it is not always easy to pay due allegiance to ethics. It takes some courage in those who have contracted the material tenets and tendencies which elementary studies in medicine are apt to engender, to admit, even in the company of Huxley, that the cosmic process has broken down and that we must go back to ante-evolutionary principles. It requires ethical strength to be ethical. Revolt has always had a charm for the young. Agnosticism has almost come to be regarded as a sign of intellectual virility, reverence as weakness of the knees. But ethical facts, which even agnosticism cannot relegate to the category of superstitions, stare us in the face, and an early recognition of their significance will help us to accommodate ourselves to our situation. Renunciation, self-discipline and respect for the rights of others and of the community not only save us from blank despair, but ensure the easiest adjustment to the existing state of things. To the medical man in actual practice a perpetual remembrance of man's ethical nature, of that in him which transcends the animal and makes for righteousness, of the union in him of *l'esprit divin* with *la bête humaine*, is of paramount importance. He has to minister to more or less ethical beings who will not be content to be treated as bits of mechanism, and the highest diagnostic skill and therapeutic precision will not save him from failure if he lacks sympathy with human suffering and frailty, and is unable to understand the emotional as well as the muscular heart. In his professional work, too, he hourly requires the support of ethical principles in himself, and of an ethical outlook to guide him amongst the subtle moral problems that are submitted to him and to support him in his resistance to the appeals of the natural man who is still the slave of his animal instincts and destitute of spiritual ideals.

Unhappily, the loose talk of the period and the literature of the day too often pander to the natural man, and extol the wisdom of following nature. It is fashionable not to be straitlaced, and great writers have not hesitated to tell us that it is the libertine who has grasped the true philosophy of life and that it is foolish to plague ourselves with remorse for acts dictated by desires of natural origin. One of our most powerful novelists, Mr. Hardy, has frequently shown a tendency to assimilate the moral to the natural, and, as Professor Seth, the present highly-gifted incumbent of the Chair of Logic and Metaphysics in the University of Edinburgh, points out, has in a conspicuous instance in his "Tess of the D'Urbervilles," sought not only to extenuate vice, but to transmute it into virtue by quoting for it a feral sanction and ensample. Tess, fallen from her innocence, is wandering in the woods, a prey to her own reflections, "terrified without reason" by "a cloud of moral hobgoblins." "Walking amongst the sleeping birds in the hedges," writes Mr. Hardy, "watching the skipping rabbits on a moonlit warren, or standing under a pheasant-laden bough, she looked upon herself as a figure of guilt intruding into the haunts of innocence. But all the while she was making a distinction where there was no difference. Feeling herself in antagonism, she was quite in accord. She had been made to break an accepted social law, but no law known to the environment in which she fancied herself such an anomaly." Now the meaning of this plainly is that the social or moral law is a mere convention, and that the true code of conduct is to be found in the woods and fields, a code in which, as I need scarcely indicate, the depths of iniquity may be legitimatised. A convention, no doubt, the moral law may be said to be, framed as it has been out of the tacit or verbal agreements of assemblages of human beings (and in the same sense some so-called animal instincts are conventions), but it is the convention that holds society together and prevents universal anarchy, and, therefore, it is lamentable to find it seriously impugned even by men of science. M. Letourneau, for instance, secretary to the Anthropological Society of Paris, contemplates with complacency the slow disintegration of the marriage tie, as evidenced by the gradually increasing number of divorces and illegitimate births in all civilised countries, and predicts that while monogamic marriage may continue to subsist, because the balance of the sexes makes it almost a necessity, it will be largely emancipated from legal restraints and become a free union, freely contracted, and, if need be, as freely dissolved. As a corollary of this freedom of marriage M. Letourneau tells us that the family tie must also disintegrate. This final collective unit of society—the family—must be broken up, and a larger collective unit—the State, the district, or the commune—must assume the *rôle* of guardian and educator of children.

I do not introduce to you such mischievous nonsense for the purpose of refuting it—that seems superfluous—but to illustrate the inevitable and pernicious consequences of including man in the strictly natural order of things and ignoring his moral obligations and to enforce my thesis that medical men are now more than ever in need of sound and definite ethical standards. I shall not be wrong in saying that, as the result of the wide dissemination of teachings and opinions such as I have quoted, the medical man is now frequently confronted by singularly confused and distorted moral views, the consequence of a kind of ethical astigmatism that is abroad. He is invited to give a professional prescription for incontinence or infidelity or a scientific indulgence to bow down in the temple of the great goddess Lubricity. He is even calmly approached in the hope of securing his assistance in a breach of the criminal law. It is not for him to be extreme to mark what is done amiss, for he comprehends better than others the infirmities of the flesh, and his pity shelters what his judgment condemns. It is not for him to scruple to adopt measures to prevent the spread of disease because, perchance, these measures might confer impunity on vice. It is not for him to censure or reproach those who seek his aid, however obviously their maladies may have arisen out of their own transgressions—that they are suffering is a sufficient passport to his skill. But it is for him when occasion arises to uphold the moral law, which is a bulwark of health as well as the chief corner-stone of felicity, and neither by connivance nor silence to countenance any infringement of purity of life. It is for him to inculcate, when the season serves, the injunction that closes the pathetic epitaph written by a wayward son of genius for himself:

> "Know, prudent cautious self-control
> Is wisdom's root."

Well, gentlemen, it only remains for me, on behalf of the seniors of the profession you have adopted, again to greet you on passing its portals, and in doing so we have nothing but words of good cheer to speak to you. We shall not, assuming the routine attitude of veterans toward beginners, tell you that

> "We, nearer to the wayside inn
> Where toil shall cease and rest begin,
> Are weary thinking of your road."

Rather we would assure you that we regard with envy the pilgrimage before you—a pilgrimage in which weariness is forgotten in the absorbing interest of the route—and that we would gladly share with you your toils, in order to be partakers in the enlightenment that is in store for you. We seem to be on the eve of great discoveries. The universe is not played out. The globe is not yet ripe for its fall. The film of organic matter that mantles on a portion of its surface is not an exhausted ferment. The possibilities of the future are infinite, and amidst the possibilities of the near future are rapid advances in our knowledge of disease and in our power of preventing it. And even if the discoveries we anticipate do not come in your time, you are still to be envied, for the career you have chosen is a beneficent and a happy one It may not bring you the rewards most coveted in these days of exorbitant luxury—piles of jaundiced metal for yourselves and bits of glistening carbon for your wives—but it will yield you an honest competency and the satisfaction of knowing that you have earned your wages. It may not raise you to social distinction, but it will reveal to you in time that there is one thing more precious than fame, and that is obscurity with work well done. Even the sad circumstances under which you must pursue your calling will not rob it of its charms. You will move daily amidst the dolorous shades of disease and will become familiar with the pallid visage of death; you will see more of sorrow and anguish than other men, and yet you will not abandon faith in life, nor will the springs of hope be frozen within you. In your incessant conflicts with the powers of darkness you will lose the dread consciousness of their stupendous power. In your practical efforts to do good, you will come to perceive "a soul of good in things evil." By the very fatigues and hardships of your lot a keener zest will be added to existence, for that bread is sweetest that is eaten in the sweat of the face. "The sovereign source of melancholy," says a brilliant Transatlantic philosopher, Professor James, "is repletion." "Need and struggle are what incite and inspire us; our hour of

Digitized by Google

triumph is what brings the void. Not the Jews of the captivity, but those of the days of Solomon's glory, are those from whom the pessimistic utterances of the Bible come." It is idle men or men of studious and reflective habits that *tædium vitæ* chiefly visits, not those who have to wrestle with strenuous responsibilities. No doubt men of melancholy temperament, constitutionally insusceptible of happiness, enter the medical profession now and then; no doubt weakly members of it break down here and there under the trials and disappointments that are incidental to it, and become a prey to misanthropical gloom; but, taken as a whole, I maintain that the medical profession is, of all professions, the most cheerful and contented. Meetings of medical men are, in my experience, all but invariably characterised by geniality and good humour, notwithstanding acute differences of opinion. The doctor's home is for the most part bright with domestic sunshine. The doctor's heart is never soured, but overflows to the last with "the milk of human kindness." I could draw a contrast, but I refrain. Let me congratulate you, gentlemen, on your adhesion to what is an anxious and laborious, but an ennobling and satisfying profession. "The claims of the future," said Lord Beaconsfield, "are represented by suffering millions, and the youth of a nation are the trustees of posterity." The future is yours. The suffering millions cry aloud for help. In the faithful execution of the trust confided to you, you will reap "an exceeding great reward."

An Introductory Address

ON

THE NECESSITY FOR SPECIAL EDUCATION IN TROPICAL MEDICINE.

Delivered at St. George's Hospital at the Opening of the Winter Session, Oct. 1st, 1897,

BY PATRICK MANSON, LL.D, M.D. ABERD., F.R.C.P. LOND.,

LECTURER ON TROPICAL DISEASES AT THE HOSPITAL.

GENTLEMEN,—I have been asked by the authorities of this school to speak a word of welcome to those of you who to-day commence your systematic medical studies. I congratulate you on two things—one, your choice of medicine for your profession; the other, your choice of St. George's for a school. Though the medical profession is by no means a bed of roses, perhaps more than any other it is one which to him who follows it in the proper spirit is full of good things. It is intensely interesting; it is a recreation as well as a study; its influence on society is rapidly increasing; it is a fairly satisfactory means of getting a livelihood; and, above all, it is full of boundless opportunities for doing good. What reasonable man could wish for more? As regards your school, apart from its associations with the past—associations such as few can boast—I can confidently claim that of all the metropolitan medical schools none have shown of late years more energy, greater determination to keep with the times, or more far-sighted enterprise. Nor have the students been unworthy of their school, for St. George's men are known all over the English-speaking world as accomplished physicians and surgeons. More than this, and in a greater measure owing to the high tone of the school and of its social life, which has been carefully cherished by the teachers, they are known as good citizens, brave soldiers, loyal and devoted public servants, and, even better than that, as gentlemen. You come therefore to an *alma mater* of honourable repute; it must be your care to maintain and, if possible, to add to this reputation. In congratulating you on your choice of a school I do so on the strength of what, since I had the honour of being connected in a humble way with St. George's, I have observed here for myself. I have been especially struck with the energy I have already referred to and that foresight in the management. In every department I find these. Naturally the institution of a lectureship on tropical medicine has appealed to me more especially; but this is, I see, only one evidence of the spirit that runs through the entire management. Laboratories, museum, teaching appliances, and teaching are all of the best and most advanced description; and I am especially pleased to remark that the students, so far as my opportunities have enabled me to judge, are not slow to avail themselves of their exceptional opportunities. The mere fact of my being asked to address you on this occasion, I believe, is but another evidence of the desire of the authorities to advance, to extend, and to improve the training they offer. They seem to be impressed with the desirability of something being done for one of the neglected departments of medical education, for tropical medicine, and as they know the interest I take in this subject I have an idea that this is the reason why I have been asked to come here to-day. I fancy I am expected to ventilate the matter. This being so, the first remark I would make is, that the systematic teaching of tropical medicine, ere many years are over, will be universal in our medical schools. Those who can read the signs of the times and who are best able to judge regard this as inevitable. Why? Because our country is the centre of a great and growing tropical empire; and, second, because tropical disease in many respects is widely different from the diseases of temperate climates, which, practically, are the only diseases about which at present the student receives instruction. There are dozens of diseases more or less special to the tropics—diseases which demand special knowledge for their diagnosis and successful treatment. Rather over a fifth part of the medical graduates of Great Britain and Ireland practise in warm climates or, being in the army or navy, may be called upon at any time to do so. Surely if tropical practice is so different from practice here it is highly desirable that this vast army of medical men should be properly equipped for their special work. It may be said, and has been said, that as the principles of pathology and therapeutics are the same the world over they apply in India as well as in England. Quite true. But we have not to do merely with the principles of pathology and therapeutics. As a practical profession we are more concerned with their application which is quite another matter. Similar objections might be, and formerly often were, raised about giving special instructions in such branches as eye disease, skin disease, and so forth, but the advance of our art and the requirements of the public have long ago swept aside these objections. So it is now with the teachings of tropical medicine as a special subject, and so in the near future it will be. A principal reason why hitherto there has been so little done in this matter is this. Candidates for medical degrees know very well that they will not be asked any questions about tropical disease by their examiners, and so they have not demanded instruction on this subject. And the reason why questions are rarely put on tropical medicine is that the leaders of the profession, those who man our hospitals, who fill the teaching chairs, who examine for degrees, who grant licences to practise, who make the regulations for the education of the youth of the profession, are, in almost every instance, men who have never practised in warm countries, and who themselves have never felt the necessity for a wider and more practical knowledge of the diseases peculiar to these climates. Not having themselves felt the want, they have been slow to acknowledge that such a want exists, and slower still to apply the remedy. But ask those who are best qualified to express an opinion on this subject. Ask the medical men who have themselves felt the responsibilities of practice in the tropics, and more especially those of them who have endeavoured to follow recent developments in tropical pathology. Ask them if they do not think that the medical man who goes out to battle with tropical disease should have some special instruction and training for the very special and responsible work he has before him, and if they do not think that the medical authorities should take care that the men who do so go out to practise should be properly qualified so far as teaching can qualify. I am sure of their answer. Unfortunately, most of the men of tropical experience live and practise away from the great medical centres. They are hardly represented on the medical teaching, graduating, or legislating bodies, and so it comes that their opinions do not make themselves felt, and that a much-needed reform is delayed. It is more especially of recent years, partly in consequence of the enormous expansion of our empire and partly in consequence of the advances in tropical pathology which have signalised the last two decades, that the claims of tropical medicine have

Digitized by Google

become urgent. Formerly the little that was known about tropical disease could be carried in a waistcoat pocket. But of late years so great has been the advance that nowadays the subject is quite as extensive and quite as special, so to speak, as ophthalmology, dermatology, gynæcology, or as any of those departments of medicine which claim and receive special teaching. More so. When the practitioner in this country is puzzled about a case it is an easy matter for him to call in someone known to be familiar with the class of case he is in trouble about. But in the wilds of Africa, in the islands of the Pacific, in lonely stations in India or China there is no consultant to fall back upon. The practitioner there has himself alone to depend upon. And woe to his patient and, if he has a conscience, to his future peace of mind if he is not up to date in his knowledge.

The course of instruction in general medicine usually received in this country is utterly inadequate to qualify for tropical practice. I say so emphatically, basing my assertion on my own experience, my own mistakes, and what I have seen and still daily see of the mistakes of others. Let me illustrate this by a few examples. Take that great scourge of mankind, greater, perhaps, than tubercle itself—namely, malaria. This is eminently a tropical disease. Every day the tropical practitioner is fighting it. Yet what does the student and future tropical practitioner actually know about malaria when he is stamped as qualified to practise his profession even in the haunts of this disease? He may possibly recognise a tertian or a quartan ague, and he may know that quinine will cure them. Ten chances to one his malarial patients know all that quite as well as he does himself. But could he, any more than his patients, tell a malarial remittent from an enteric fever; could he diagnose a pernicious malarial attack from cholera, it may be, from thermic fever, from apoplexy? He has heard of the malaria germ, but has he seen it; could he recognise it; has he been taught to find it for himself; to make use of the fact of its presence or absence in the circulation as an infallible means of diagnosis? What would an examiner nowadays do with a student who could not recognise and demonstrate the tubercle bacillus? He would pluck him. At all events, were I an examiner I would pluck him. And if I were an examiner and found that a student, intending by-and-by to practise in the tropics, could not recognise and demonstrate the malaria parasite I would do the same. For I know that the malaria parasite is just as important to him and his prospective patients as the tubercle bacillus is, and that the ability to recognise and demonstrate it is just as necessary for the tropical practitioner. In those terrible sudden forms of malaria which now and again will be sprung on him perhaps the only reliable means of diagnosis lies in ability to recognise the malaria parasite. Life hangs on it. Dr. Andrew Davidson, whose experience in tropical medicine has been very great, and whose judgment and knowledge are on a par with his experience, on my telling him I was to speak about these things to-day, and sympathising with my views, at my request sent me some memoranda on the subject. He relates a case which well exemplifies the necessity for knowing something about malarial disease before attempting to treat it. He writes: "I had not landed many weeks in Madagascar when I was called upon to see a patient who, I was told, had been suddenly seized with what was looked upon as an apoplectic fit. This was in the afternoon, and when I saw him about an hour afterwards he was lying unconscious, the body in a state of complete resolution. The skin was cool, the pulse and respiration were slow, and there was no stertor. His condition suggested cerebral hæmorrhage or thrombosis. It was, indeed, in a certain sense a case of thrombosis, for, as it turned out, the patient was suffering from the apoplectic form of pernicious malarial seizure, in which, as we now know, certain capillary areas in the brain are permanently or temporarily blocked by malarial parasites and pigment. The disease is by no means a rare one in malarious countries. It had long before been described by Torti. I had read in Graves's Lectures of the soporose or comatose seizure, in which fever is a prominent symptom. Here there was no fever, and the possibility that it was a malarial attack never entered my mind. What the precise brain lesion might be I could not decide. But something had to be done, and I saw nothing better than to place a drop of croton oil on the tongue, apply a blister to the nape of the neck, and warn the relations to prepare for the worst. I was gratified to hear next morning that, after remaining ten hours insensible, the patient had recovered consciousness; but what surprised me most was that there was no paralysis. The patient's chief complaint, in fact, was the blister. In the afternoon of the same day the patient was seized with shivering, fever, and sweating. There could now be no difficulty either as to diagnosis or treatment. The patient probably owed his life to the fact that the apoplectic seizure did not recur and prove fatal, as it often does when treated on the lines I had followed. What I conclude from this is that grave mistakes would often be obviated by special instruction in tropical medicine." Dr. Davidson remarks: "Experience, no doubt, is a good teacher, only the fees are very heavy." The microscope would probably have diagnosed this case correctly, but then one must be taught how to apply it.

I could relate from my own experience many similar stories illustrative of the danger to life with which a working experience in malaria has been bought. As with malaria, so with many less important, though nevertheless very important, tropical diseases. What, I would ask, does the student learn of practical value about beri-beri, a disease which, if he is to practise in the tropics, he is almost sure to encounter often enough, although he may not recognise it when he does come across it? Beri-beri is a very important malady. Occurring both endemically and epidemically it annually kills its thousands and tens of thousands. It makes the settlement of many fertile lands almost impossible. It kills off the planters' coolies like flies and makes his plantations unprofitable. It fills the hospitals and is a downright scourge in some of the fairest lands of the earth. But it is a disease which can to a great extent be prevented; and it is a disease which can by proper management be robbed of much of its danger. Its recognition, therefore, is of the first importance. Many times, in beri-beri perhaps more than in most diseases, early and correct diagnosis means the saving of life. When I first went to the east all I knew about beri-beri was its name. This I had sometimes seen in books. I had wondered at its quaintness; perhaps, medical student-like, I had waxed facetious about it and had punned upon it. So little did I know about beri-beri that I believed some medical writers who said that it was a kind of anæmia. Examiners, I was told, were not likely to ask any troublesome questions about the symptoms, pathology, or treatment, so I skipped the chapter on beri-beri in "Aitken's Practice of Medicine" as being for my immediate purpose useless. Students then, as I suppose students now, worked to pass their examinations as their primary object; to learn their profession was altogether a secondary affair. Little wonder, therefore, I failed to recognise the disease when I first came across it. I well recollect my first case, and the horror and the shame with which it filled me, and still fills me. I was then in practice in Formosa. One day I was called to see a Chinese clerk employed in a European firm. I had known him well as an active, obliging young fellow. I found the patient sitting propped up in a chair, short of breath, dropsical from head to foot, with a cardiac bruit, irregular, tumbling action of the heart, and complaining of a feeling of distress in his chest. As there was no albumin in the urine, and as there was a loud bruit with manifest disturbance of the heart, I felt convinced it was a case of heart disease, and from other circumstances in the case one which treatment would benefit. I prescribed and gave directions, and went away feeling, and probably expressing by my manner, that we Europeans knew a great deal more about disease than the old Chinese doctor who hitherto, with the assistance of the village idol, had been treating the patient. Next day I went to see the lad expecting to find an improvement. I thought as I passed the door that there was a strange hush about the house. I entered what was my patient's room. On the bed, covered with a blanket, there was something long and rounded and still, which explained the hush I had noticed; and so I left the house sadder, wiser, and, I trust, humbler than I did the day before. Some years later, being then in general practice at Amoy and in charge of a large native hospital, I used to see a number of Chinese soldiers who came to hospital suffering from what appeared to me, in my ignorance, to be locomotor ataxia. Some could hardly walk, others could just stagger into the out-patient room, and some had to be carried in. The significance of the knee-jerk symptom in spinal disease was then a new discovery, and in those days was regarded as a sure sign of locomotor ataxia. In all of these soldiers the knee-jerk was absent, and all of them exhibited what I took to be ataxic symptoms. If you would criticise

Digitized by Google

my diagnostic acumen please bear in mind that in those days peripheral neuritis had not been invented. However that may be, I diagnosed these cases as locomotor ataxia, prognosticated that they would never recover, declared that there was no immediate danger to life, put them to bed, and prescribed strychnine in various forms. But by-and-by, in utter disregard of my prognosis and of my reputation, in the course of a month or two some of those soldiers whom I had regarded and pronounced as hopeless cripples were walking about; some had even returned to their military duties. This is the pleasant, not to say the funny, side of my mistake. There is another side, however—one not quite so funny. A good many of these patients died—died suddenly, just as my dropsical Formosa patient had done. I was mortified as well as puzzled. What was the nature of these cases? My books did not help me. I noticed that whereas some of these paretic patients were wasted to shadows, others were swollen and œdematous. I also noticed that in most of them the muscles, especially the calf muscles, were tender. Occurring as this disease did as an epidemic, and confined to a very limited area (for most of the cases came from a damp, ill-constructed fort, the casemates of which served as a barrack), and knowing that the Chinese are very fond of pork, I thought that the muscle tenderness and the œdema might be symptomatic of trichinosis. I thought I might be dealing with an epidemic of trichinosis. Indeed, I went the length of searching the muscle for trichinæ. If they can help it the Chinese will not allow their dead to be dissected. I always entertained a great respect for what we in our civilised pride call "native prejudices"; but in this instance, in view of the importance of correct diagnosis, I thought I would run the risk of offending these for once. So with the aid of an old and seasoned native porter I smuggled one of the dead bodies into a piece of waste ground near the hospital, and there behind a wall excised a piece of muscle. Needless to say I found no trichinæ. In this way I groped about for a long time in search of a diagnosis. It was not till months had elapsed and not a few deaths had occurred that I recognised that I had to deal with an epidemic of beri-beri, and it was only then that it began to dawn on me that the poor dropsical fellow who had died in Formosa some years before had really died from beri-beri and not from heart disease after all.

For exactly the same reason—lack of proper teaching—the history of my education in the matter of beri-beri is that of most of the medical men of my generation who, in lonely places in the tropics, essayed to practise their profession. And I am grieved to say that in this matter even at the present day it is just as it was thirty years ago. My education in beri-beri was got by experience; the young medical man of the present day has to learn in exactly the same costly way as I did and in the same stern school of experience. As Dr. Andrew Davidson says in his letter to me, "The fees are heavy." Only the other day I got to know that there had been no improvement on the teaching of beri-beri in all these thirty years. This is how I came to realise the ugly fact. Beri-beri is very common, you may be astonished to hear, in the port of London, especially among the lascars and seedy boys who in many instances form the bulk of the crews of the large steamers trading to the east. The cases are often brought to the Seamen's Hospital. They come on written medical recommendation and are sent as cases of heart disease, kidney disease, almost anything but beri-beri. They are very rarely correctly diagnosed. Now the ship-surgeons who make out the certificates are usually men fresh from the schools and from their examinations, and therefore, presumably, well up in all that is newest in medicine. Here is a verbatim enumeration of some of their diagnoses: anasarca, rheumatism, pericarditis and fits, dyspnœa, cardiac disease, debility, asthma and anasarca, Bright's disease, locomotor ataxia, myelitis, tachycardia, apoplexy, paraplegia, progressive muscular atrophy, and, of course, hysteria. I transcribe these diagnoses from the admission registers. Not once in a dozen instances is the diagnosis correct. Now it does not matter so much whether the cases are correctly diagnosed or not provided they are sent to hospital. But there is every reason to believe that many of the cases of ship beri-beri are not sent to hospital, but are treated on board their ships, and that many die in consequence. When we admit a case of beri-beri from a ship we ask if there are any more cases of the disease on board and if there have been any deaths. We are generally told that there are no more cases on board, but that there have been deaths from heart disease, asthma, or some such name, which from experience we know under the circumstances stands for beri-beri. Sailors, we may be sure, are not shipped with active heart disease or with asthma such as would be likely to have a speedily fatal issue. I heard of one instance of a lascar who had been shipped in India as an effective seaman. Within a few weeks he died on board ship, and the cause of his death was officially logged as locomotor ataxia; as if locomotor ataxia ever ran its course in four or five weeks. The man died from undiagnosed beri-beri as many others have done. All this represents a very serious, not to say disgraceful, state of matters. Most of these deaths are avoidable. No beri-beric should be allowed to remain in the place, whether house or ship, in which his disease was contracted; to allow this is like treating a case of alcoholic neuritis with brandy. To treat alcoholic neuritis properly you must first diagnose it, and similarly to be able to treat beri-beri properly you must also first diagnose it correctly. But without special instruction or without an experience bought with human life there is as little chance of being able to diagnose the one as there is to diagnose the other.

Filariasis is another tropical disease which is often overlooked, and about which there are many absurd and even dangerous misconceptions. In most tropical countries in which the subject has been investigated it has been found that about one man in every ten is affected with blood worms. In some places the proportion is as high as one in three, in others one in two, and I know of at least two places where nearly every inhabitant is victimised in this way. Surely, therefore, it is of importance, seeing that these parasites give rise in many instances to grave disease, that the medical practitioner should know something about them, be able to diagnose their presence, and recognise their effects. But ten chances to one if one asks a student, or even a medical practitioner, to set about examining a patient for filariæ he will prepare a very fine film of blood, such as would be suitable for the demonstration of bacteria, and that he would set to work to examine it with a twelfth of an inch immersion lens and an Abbe condenser. Now, although there may be tens of millions of filariæ in the patient's blood the chances are they will not be discovered by such means. Most people think that when they have to make a microscopic examination the more microscope they have the better. As a rule, the reverse is the truth. Filariæ should be sought for with an inch objective, otherwise they will be missed. Though the individual filariæ are large as compared to bacteria they are relatively few in the blood. You require, therefore, to include a large field with your microscope to have a reasonable chance of finding them. If a sailor could command with his eye only the narrow horizon visible from a small boat he is not likely to see many whales in the sea, so he ascends into the crow's-nest at the mast-head, and, commanding there a wide view, he can see any whale that spouts for miles around. So it is in searching the blood for filaria—a large field is indispensable. But this is a self-evident fact hardly ever grasped by the student unless he has it actually demonstrated to him. He seldom arrives at it spontaneously. Now, exactly the opposite is the case for the malaria parasite. All this needs teaching, needs demonstration. The malaria parasite I tried to find for nearly ten years before, through accident, I finally succeeded. A Chinaman found my first filaria for me. I mention these things to show how necessary it is, if we would save time and make the best of our opportunities, to have someone to teach us even simple technique.

In connexion with filariasis and blunders in diagnosis from want of elementary instruction in tropical disease I may refer to a case which I came across. The patient was a handsome young fellow, who some years before had joined a regiment of horse artillery then in India. He got on very well for a year, liked his work, and was on the high road to promotion. One day he got a smart fever, and with the fever a pain in his left groin, which he now and for the first time noticed to be swollen. In due course the fever subsided; not so the swelling, which grew and grew until it became the size of a fist. It interfered with his riding, and so he consulted the regimental surgeon. The swelling was soft and to a certain extent reducible. Accordingly rupture was diagnosed and a truss applied. But the truss caused so much pain that it could not be worn. It irritated the swelling, and brought on attacks of inflammation and fever. Getting no better he went to one of the Presidency towns to consult a surgeon of experience in tropical disease. This surgeon recognised at once the true nature of

Digitized by Google

the swelling, diagnosed the case as one of varicose groin glands, confirmed his diagnosis by an examination of the blood, which he found to be full of filariæ, and very properly advised the patient to throw away his truss and to give up soldiering. Now a very little instruction in tropical disease given to the regimental surgeon would have put him on the right track, would have spared this patient much suffering, time, and expense, and have reduced to some extent the military burdens of our over-taxed Indian empire.

One more illustration of my contention. In 1895 and again in 1896, Mr. Galgey, colonial assistant surgeon, St. Lucia, West Indies, sent certain valuable reports to the Government, part of which were subsequently published in one of the leading medical journals, pointing out that ankylostomiasis is very prevalent in St. Lucia and probably all over the West Indies, and narrating his experience of the wonderful efficiency of thymol as an anthelmintic. As many of you are doubtless aware, there is a form of pernicious anæmia common among negroes and the natives of hot countries generally. The patient, without obvious reason, becomes breathless, weak, anæmic, dropsical, and very likely, after a long and distressing illness, dies. Many years ago Griesinger showed that the Egyptian form of this disease was associated with—in fact, caused by—a blood-sucking intestinal parasite—the ankylostomum duodenale. In 1880, in consequence of the publicity given to this discovery by the epidemic of ankylostomum anæmia among the workmen in the St. Gothard tunnel, this fact of the relation of the ankylostomum to a form of pernicious anæmia was thoroughly established. In the same year Bozzolo introduced thymol as an anthelmintic in this helminthiasis. Experience in Jamaica, Ceylon, Java, Brazil, the Straits Settlements, and elsewhere confirmed Griesinger's discovery of the cause of this anæmia and also Bozzolo's discovery of its curability by thymol. But although these things were well known in Italy and in many parts of the tropics their importance was missed by the teachers of medicine in England, and as a consequence the medical men who went out even subsequently to 1880 to the West Indies went out imperfectly informed in a matter of the highest importance to a considerable section of the people committed to their charge. Thus our fellow subjects, the poor negroes, did not have the benefit of an important advance in medical science and in practical therapeutics until Mr. Galgey found, fifteen years after it was known in Europe, that ankylostomiasis was the cause of the anæmia of the negro, and that thymol could cure it. Who can estimate the number of lives that might have been saved if tropical medicine had been taught to our West Indian colonial surgeons and if they had gone out thoroughly informed on the subject of ankylostomiasis? Mr. Galgey writes that in the six years 1890–95 there were 72 deaths in the hospital of Castries, St. Lucia. In the year 1896—that is to say, since he diagnosed the nature of these cases and treated them efficiently—he informs us that there was not a single fatal case of this disease. From this we are entitled to infer that the seventy-two deaths from pernicious anæmia occurring in the preceding six years were from ankylostomiasis, and that these seventy-two lives might have been saved. That is to say, an average of twelve lives a year. Or, assuming that this mortality had been going on ever since 1880, the date of the discovery of the anthelmintic properties of thymol, we must conclude that in the hospital of Castries alone 180 people died whose lives might easily have been saved. But this is not all. There are four or five hospitals and dispensaries in St. Lucia, and as there is no reason to suppose that ankylostomiasis is confined to the Castries district of the island we are forced to conclude that in these fifteen years about 900 have died unnecessarily in St. Lucia. St. Lucia is one of the smaller West India islands. Although I know that thymol has been in use for some time in British Guiana, I do not know that, except in the hospital in Kingston, Jamaica, it has been generally employed in the neighbouring archipelago. I also know that the existence of the ankylostomum has not been recognised, at all events until very recently in many of the islands. The avoidable mortality from ankylostomiasis therefore for the whole of the West Indies during these fifteen years must run into tens of thousands. This is a serious indictment against our present system of medical education, and the worst of it is that what holds good for ankylostomiasis holds good for a dozen other tropical diseases, some of them perhaps not so serious as ankylostomiasis, but some of them even more serious.

I fear that, as so often happens in medical lectures, I have spent so much of my hour in describing the symptoms and pathology of this disease of the body medical that I have little time left in which to speak of that very practical matter, the treatment. I hope, however, I have convinced you that we are speaking of a very grave disease in our educational system, and that there can be no question about the diagnosis and the indications for active and prompt treatment. I have my own ideas about the latter, but as the responsibility in the case is serious I have called in a specialist of experience to prescribe. I need hardly say I fully endorse his prescription. Dr. Andrew Davidson writes: "I do not think that attendance on a course of lectures on tropical medicine should be made a part of the ordinary curriculum. It seems to me, however, urgently necessary (1) that a course of lectures on the hygiene and diseases of warm climates should be instituted in each medical school; (2) that a certificate of qualification in these subjects be granted by the licensing bodies after examination to those who have attended this course of lectures; and (3) that the Government should encourage the study of tropical pathology by giving a preference to those possessed of this certificate if equally proficient in other subjects, and that appointments made from home of medical officers for tropical and sub-tropical colonies should be restricted to men holding this qualification." If these suggestions are acted on, not only would vast benefits accrue to the natives of warm climates and to those Europeans who have to reside among them, but an enormous impetus would be given to tropical pathology and therapeutics, and, doubtless, indirectly to medical science in general. By instituting a lectureship on tropical medicine St. George's Hospital has done its share in encouraging this necessary reform in medical teaching. Other schools are following our lead; but be the schools ever so willing to second each other without the coöperation of the General Medical Council they can do but little. As Dr. Davidson suggests—and it is the General Medical Council that can alone give effect to the suggestion—there should be a special examination and some kind of diploma for tropical medicine, and Government should countenance and encourage it. If this reform be carried out of one thing I am sure, and that is that those of you who in the future may go abroad to practise your profession will bless the General Medical Council for forcing you to qualify yourself for your work.

INTRODUCTORY ADDRESSES, ETC.,
DELIVERED AT THE
LONDON AND PROVINCIAL MEDICAL SCHOOLS
AT THE
Opening of the Session 1897-98.

UNIVERSITY COLLEGE, SHEFFIELD.

INTRODUCTORY ADDRESS BY DR. PYE-SMITH, F.R.S.

AFTER congratulating Sheffield on the union of Firth College and the Medical School to form the new University College, and on its approaching admission as a constituent of the Victoria University, Dr. Pye-Smith referred to the history of university education in England. The mediæval universities of Bologna and Padua, Salamanca, Paris, Oxford, Leipzig, and Wittenberg were succeeded at the revival of learning by the foundation of many new ones on the continent of Europe. The four national universities of Scotland were founded during the same period between the end of the fifteenth and the beginning of the seventeenth centuries. In the sixteenth century also were founded many of the colleges at Oxford and Cambridge and the University of Dublin. But it was strange that in the six centuries of national development which extended from the time of Magna

Digitized by Google

Charta in 1215 to the time of Waterloo in 1815 no university was founded in England. These northern counties were comparatively poor and barbarous until modern times, but it was remarkable that there had been no University of York, of Norwich, Bristol, Exeter, or Canterbury. The two great secular professions of law and medicine had their own history and their separate development, and neither Pope nor King gave a third university to England. During the long and prosperous reign of our revered sovereign much had been done to make up arrears. University and King's Colleges and the University of London, Owens College at Manchester, Mason College at Birmingham, and the University Colleges of Bristol, Leeds, Liverpool, Nottingham, Newcastle, and now of Sheffield have successively arisen; and within the memory of all present the Victoria University (of which all present formed members) and the more recent University of Wales have been founded by Royal Charter. Enough probably had been done for the present in constructing the framework for higher education in England. Accumulated endowments were still needful and the working out of the federal type of university. If he might offer advice drawn from the chequered and still uncertain fortunes in London he would say—trust to local wealth and public spirit and avoid Government grants as much as possible. Beware of the utilitarian spirit; let adequate provision, personal and material, be made first for literary and scientific research, secondly for education, and thirdly for technical instruction. The reversed order was the easier, but in the long run he ventured to think the less fruitful. While the moderating influence of statesmen and men of business and the interest and support of past students and graduates would find a valuable place in the constitution, let the chief responsibility rest upon those actually engaged in teaching and research. And in settling provisions of charters, respective powers of colleges and terms of graduation, everything should be done to decide these questions for themselves or by independent visitors, royal commissioners, or arbitrators chosen by the Crown from men of experience in university matters, and not by the inscrutable counsels of ministers and the meddling of individual Members of Parliament. Dr. Pye-Smith then went on to speak of the two senses of the word knowledge, both of them the objects of attainment by students of a university. The desire for knowledge how to do something is historically the earlier and is shared to some extent by the lower animals. Its end was subjectively the partly physical, partly intellectual pleasure of exercising the muscles and brain, objectively the attainment of some useful object. Such knowledge was called skill or art, and the man who attained it was a skilled workman, an artisan, an artist, a master of his craft. The continuity of this kind of knowledge depended on tradition, and its improvement was by invention. Its acquirement was called technical education; its results were seen in the products of agriculture which feed us, in the ships and railroads which carry us round the globe, in the triumphs of steam and electricity, of preventive medicine and antiseptic surgery, in the matchless steel, the wondrous armour-plates, and all the vast output of the skilful industry of Sheffield. But there was another kind of knowledge—the desire for which came later in human history—the knowledge of what things mean, of how they consist, of why one event follows another. This knowledge was not active, but contemp ative, not practical, but theoretical, not technical, but scientific. Its end was purely intellectual; subjectively, the pleasure of exerting the mental powers by which the Creator had enabled us to understand a portion of His ways; objectively, the truth about things. We call this knowledge science; that is, not only acquaintance with the objects around us, or natural history (descriptive botany, zoology, mineralogy, geology, astronomy, and anatomy), but also some insight into their constitution and growth, into the laws of their origin, their actions, their decay and metamorphoses. This was called natural philosophy. Its improvement depended, not on invention of tools and methods, but on discovery of facts and their relations. It was only indirectly useful, and the pleasure it gave was in proportion to the intelligence of the man who felt it: "*Felix qui potuit rerum cognoscere causas.*" The abstract sciences seem to have arisen out of the needs of useful arts—geometry out of measuring the rising of the Nile, arithmetic out of counting the hosts of a Persian despot or the gains of an Indian money-lender, trigonometry out of setting landmarks, chemistry out of the alchemist's search after gold, botany out of materia medica, and anatomy out of surgery. Amply has the debt been repaid. At the present time all the progress in useful arts was called "scientific," and rightly so, for all depended upon natural science. Agriculture rested on the basis of organic chemistry, geology, and botany, navigation on astronomy, the working of metals on physics and chemistry, engineering on mathematics, medicine on physiology, and if ever the art of governing mankind was to be more than empirical it would rest on profound knowledge of paleontology and neurophysiology. What, let us ask more particularly, are the objects and what the limits of natural philosophy? We must give up as beyond human powers all knowledge of real existence, of the true nature of things, of an essential "substance" underlying all phenomenal accidents. On this quest the ancient philosophers went astray "and found no end, in wandering mazes lost." In the same labyrinth the nominalists and realists, and the acute mediæval schoolmen argued and deduced and syllogised. Their labour was not wholly lost, it sharpened men's wits and it set up a warning sign-post inscribed "No thoroughfare." If, however, it was determined to believe nothing but what your senses tell you, the first lesson of physiology was to distrust the perceptions derived from the eyes, ears, and fingers. Our senses do not bring us directly in contact with matter, they only offer us "signs," which by experience we learn to combine and interpret as connoting material objects. And suppose you have forced all phenomena, even those of thought, into a material formula, what evidence have we that matter exists except states of consciousness? So that extreme materialism and extreme idealism meet in an insoluble contradiction, like that between fate and freewill. No science is absolute, not even mathematics, for this does not deal with real objects, but with lines without breadth, with rods which never bend, and cords which never stretch. The only knowledge attainable by man was not abstract but concrete, knowledge, not of existence, but of phenomena. It depended not on deduction from axioms and postulates, but on generalisation from observed facts, not on syllogisms, but on experiments. The results of science were approximate, tentative, constantly liable to correction, expansion or limitation by fresh evidence; and they were not absolute, but only probable. Its method was first accurate, repeated, accumulated observation of facts, under the same and under varied conditions, next some generalised statement, then more intentional, varied conditions or experiments designed to verify or disprove the statement. Gradually the results of observation and experiment become of more and more general application, and at last some rule was found to be so constant and far-reaching that it was called a law. But this, again, was a word to beware of. It was a law only until it was broken. The constancy of species was such a law, and it was quite right for Cuvier and the best naturalists of the former half of this century to hold to it against the speculations of Oken and Lamarck and Erasmus Darwin and Geoffroi St. Hilaire, against the followers of the Naturphilosophie and the evolutionists before the greater Darwin arose. Lyell and Hooker, who disputed the doctrines of their eminent friend until he brought fresh and fresh evidence which inclined the scales of probability, were right up to that point to resist, after that point to accept, the origin of species by natural selection; for the duty of a philosopher was not to make a number of clever guesses, like the wise men of Greece, in the hope that one or other may hereafter turn out right, but to follow evidence to its most probable conclusion. Dr. Pye-Smith then referred to a certain kind of judgment which might be regarded as approximately true and certain, although it could not be proved as a scientific result. It related to matters of morals and of taste which have the consensus of varied and competent opinion. For instance, it might surely be said of the Œdipus Coloneus that it was admired by the highly competent fellow countrymen of the author at the time; that it had been admired by every generation since and in every country, and in proportion to the prevailing study of poetry in general; and that it was most admired by those who were themselves poets as well as critics. The same applies to all classical works of art, to Grecian sculpture, and to Italian painting. Surely we may say that it was as certain as any scientific fact that Sophocles was a great poet, Phidias a great sculptor, and Titian a great painter; that as long as human beings call roses sweet and the starlit heavens glorious, so long will the names, the renown, and the praise of these mighty makers endure.

Digitized by Google

The proof of scientific statements was that they came true. The farmer within limits can count on the result of manuring his land and crossing his breeds of cattle. The engineer can, also within limits, rely on the strength of the bridges which he has constructed by aid of mathematical calculations. The physician can, again within limits, foretell the result of a certain morbid process and of a certain preventive or remedial agent. In conclusion Dr. Pye-Smith cautioned against excessive deference to authority, against the intrusion of metaphysics, metaphor, and rhetoric into scientific discussions, and against facile explanation instead of rigorous investigation. He dwelt on the importance of actual contact with materials and apparatus, and the direct study of the original statements of authors. He urged the value of putting all the energy and effort possible into every bodily or mental exercise. "In speaking, in writing, in reading, choose always the best, and in working or playing always do your best. Find the true happiness of energetic exercise of your powers. We know how in mountain-climbing, in rowing, or in any continued exercise the breath fails and the muscles are tired after a time; the temptation to cease effort seems irresistible; but we know also that if we go slowly and doggedly on, the second wind will come, the heart beats steadily again, and we find our powers renewed. So mental efforts have their dull and irksome periods, but if we go on *doucement mais toujours* difficulties yield and perseverance conquers. We have each of us his own appointed limits. If you train you will be able to leap many inches higher than you could at first, but the rapid progress of the first week or two becomes gradually slower, and at length no further practice, no effort of the will, suffices to increase the height you can jump. So it is with mental work; by effort and by practice we can each increase our powers and improve our results. But we shall find our quickness and accuracy of observation, our sureness of judgment, our insight and power of reasoning have their limits. I promise you therefore no impossible results. Each in his own order. You will still look up to the heights attained by Newton and Faraday, by Pascal and Lavoisier, by Helmholtz and Ludwig, with increased, not diminished, admiration, because you have climbed a little higher. But the prize is not in the result—*Labor ipse voluptas*. The strenuous exertion of the powers you possess, the faithful use of the one or the many talents entrusted to each of us,—this is the immortal garland to be won, not without dust and sweat. Each of us has his own powers and they are equal to the duties of each. We may not, we dare not, decline the contest or drop out of the race. For we are set like sentinels, who watch through starless nights and wait the appointed hour, and we can never enjoy the full happiness of active exertion of body and of mind, the pleasure of work and the pleasure of rest, the tranquil heart, the sunshine of the breast, unless we do our daily work

"'As ever in the Great Taskmaster's eye.'"

ROYAL VETERINARY COLLEGE.

INTRODUCTORY ADDRESS BY MR. D'ARCY POWER.

Mr. Power began his address by extending a cordial welcome to the veterinary students who were now commencing their work at the College. They had chosen their profession wisely, for veterinary science was advancing more rapidly than any other branch of the healing art. It was daily obtaining a higher place in the eyes of the State and of private individuals as one of the most useful professions both to the wealth of the country and the welfare of the community. He then continued: "Charles Sainbel, the founder of the Veterinary College, taught human anatomy a lesson and at the same time established his own reputation in England when he published his essay on the proportions of Eclipse (the great racehorse belonging to Mr. O'Kelly), who was never beaten, and who died on Feb. 27th, 1789. The essay is still in advance of the time, for it shows how animal mechanics can be expressed in geometrical terms, and it would be interesting to apply Sainbel's methods to the record-breakers who are now so numerous in the world of athletics. The observations of veterinary anatomists, too, explain many obscure points in connexion with the development and anatomy of man, especially in those aberrant conditions which are found to a greater or less degree in every body which is carefully dissected. The debt of human physiology to veterinary physiology is well recognised. In modern times and in this country it dates from the day in 1727, when Archdeacon Hales introduced a long tube into the femoral artery of a horse, and noted the height to which the blood rose in it. The importance of breeding has led veterinary surgeons to make a most careful examination of the generative functions in animals, and has enriched physiology with many facts of prime importance. It has demonstrated the possibility of artificial impregnation; it has settled the vexed question of superfecundation, and the recent work on epizootic abortion has set us thinking whether a similar condition may not occur sometimes in the human species. In like manner histology owes much to the study of animal tissues, for until recently nearly all the human tissues have been examined either in a diseased or badly preserved state. In botany veterinary science has long placed medicine under a debt of gratitude. All practical men, whether physicians or veterinary surgeons, have had occasion to study the effects of poisonous plants, and the results obtained from observations on animals have often been of signal service to the medical profession. Veterinary science has done more than this, for it has compelled botanists to study the most difficult but important natural order of the grasses, not only from a classificatory standpoint, but in such a manner as to indicate the economic value of the constituent genera. Veterinary medicine sometimes gives valuable hints to the human physician about the use of drugs and the cause of treatment of various diseases, which, though they are common to men and animals, are more common in animals. Until quite recently, however, the importance of veterinary science to physicians has never been better shown than in connexion with the life-history of the more common entozoa, some of whom use our bodies as an intermediate host in the cycle of their existence which they renew in cattle, dogs, or rodents. The surgeon has learnt somewhat less from the veterinarian than any of his brethren who practise upon the human body, yet even he has learnt a few principles from the veterinary surgeon which have stood him in good stead in the advancement of his art. The operations of the sow-gelder stimulated the early ovariotomists to practice a similar operation upon women, and encouraged them to persevere, in spite of the most disastrous results, until the operation was brought from a position of complete disrepute to the high place which it now occupies in the estimation of surgeons. Indeed, it has always been in principle rather than in detail that medicine has been indebted to veterinary science. Nowhere is this better seen than in pathology. Every first-rate pathologist is necessarily a man of science, a comparative pathologist with a wide knowledge of animals as well as of men. It is this fact that has made pathology the grandly progressive science which it has lately become. John Hunter was interested alike in men and cattle, but his successors for many years were mere morbid anatomists concerned with the details of morbid processes, not with their principles. It is only recently that we have outgrown this stage and have become pathologists in the true sense as disciples of Hunter, who must always remain our great master. In pathology human medicine has learnt from veterinarians the great lesson, long since known to the Preacher, but long since forgotten—"For that which befalleth the sons of man befalleth beasts, even one thing befalleth them; as the one dieth, so dieth the other; yea, they have all one breath; so that a man hath no pre-eminence above a beast." The better and wider knowledge of pathology possessed by the best veterinary surgeons often helps them to settle very obscure points in connexion with disease occurring in the human being. It is no wonder, therefore, that comparative pathology daily rises higher in the estimation of the medical profession, for to the thoughtful physician its problems appear to be identical with the most difficult which he is called upon to solve. Daily, too, we see that prophylaxis is the most important part of medicine, and it is exactly in prophylaxis that comparative pathology excels, though it has done good service in pointing out the part played by animals in sharing diseases which affect man. In doing so it has shown that animals may act as transmitters of disease, so that cats and pigeons in diphtheria, horses in influenza, and rats in the plague, must be considered as probable rather than as possible carriers of infection. Prophylaxis is of as much importance to a large stock-owner as it is to the head-master of a public school; and a thorough knowledge of preventive measures is even more valuable to a veterinary surgeon than it is to a physician. Only in exceptional cases will an owner consent to pay for the treatment of a prolonged illness in his stock, whereas a human being must be attended

Digitized by Google

throughout his sickness, for he cannot be summarily slaughtered. But all preventive measures on a large scale require special knowledge and concerted measures. Special knowledge only accumulates slowly; concerted measures require the intervention of the State. After many years the Government in this country was made to feel the necessity of enforcing the application of sanitary measures and medical officers of health came into existence. In a tentative manner and very incompletely some attempts have been made to form a veterinary sanitary service. But too much is left to the initiative of local bodies, and what has hitherto been done in detail now requires to be established upon a broad groundwork. Such a service properly conducted would be of undoubted use to the community, whilst it would be advantageous to the veterinary profession. The whole of animal hygiene should be placed under the care of a veterinary sanitary service, and as no one can be much in advance of his time such a service for the present should be carried out along the lines which have been found most useful in the medical sanitary service, care being taken to eliminate or, if they cannot be altogether eliminated, to strengthen those points which have seemed to be the weakest in the working of the Public Health Acts. Such a veterinary sanitary service would not be hard to organise. Its existence is already foreshadowed, for the state has recognised that a medical officer of health cannot be omniscient. The Infectious Disease (Prevention) Act of 1890 allows the medical officer of health to be accompanied by a veterinary inspector or some other properly qualified veterinary surgeon to inspect the animals supplying milk to a suspected dairy. Such officers should be much more carefully trained to enable them to perform their duties efficiently, and after a proper course of training, being duly qualified veterinary surgeons, they should be able to obtain a diploma in veterinary hygiene. A specially qualified body of men being thus provided, places would have to be found for them throughout the country. At first, no doubt, this would be difficult on account of the expense, but the stock-owners form so large and important a body of men that as soon as they had satisfied themselves by actual proof that such a system saved them from loss they would readily assist in its extension. The districts over which the veterinary sanitary officers would have to preside should be large enough to occupy their whole time, whilst the remuneration should be sufficient to tempt the most promising of the young men to apply for appointment. There should also be provision for a reasonable security of tenure. Only the very best men should be advised to enter the veterinary sanitary service at first, for they will have to create the service. They will have to fight and to overcome many difficulties both of fact and prejudice. Not only will the public be opposed to them, but as some of their duties must necessarily overlap those of the medical officers of health there is certain to be some jealousy between the less competent and more narrow-minded members of the two services. The more highly educated and the more far-seeing members of the medical profession, knowing the disadvantages of dual control, will readily yield to the veterinary service those duties which seem especially to belong to it, and they will welcome a release from comparatively alien subjects, as it will allow them more time for the effectual performance of their own work, which is already sufficiently arduous. The duties of the veterinary sanitary officers would be to carry out the provisions of the Animals Contagious Diseases Acts and of the Dairies, Cowsheds, and Milkshops Orders of 1885 and 1886. They would also inspect piggeries, the slaughter-houses and butchers' shops, and they should be given effectual control over all meat exposed for sale. By a careful system, too, of notification, followed by immediate inspection, they would be able to control many contagious diseases, whilst a better system of registration and the destruction of ownerless dogs throughout the country would soon render hydrophobia as rare in England as is leprosy. The veterinary sanitary officers having to control large districts would necessarily require assistance, which would be provided by recruits from the class who now furnish the veterinary sub-inspectors—reliable men who have held positions of trust in the district, and who are therefore well acquainted with the local inhabitants and their customs. Even these men, however, should receive some course of training before they enter upon their duties. The veterinary inspectors would remain, for they have done good and useful work; but as vacancies occurred their successors would be selected from the most energetic and tactful of the veterinary sanitary officers, who would be tempted by the prospects of better pay and wider duties. The veterinary inspectors would form a more select body of men, specially qualified to sift evidence and fitted by the highest scientific training to cope with the more formidable outbreaks of epizootic disease. They would be responsible to the Department of Agriculture whilst the veterinary sanitary officers would be under the control of the County Councils. Both classes of officials should be wholly occupied in their duties and should be prohibited from private practice lest there should be even a suspicion that their interests as individuals might clash with the efficient performance of their public duties. The surest way to ruin the service would be to make a series of small appointments; but if a service of well-trained men devoted their whole energies to the study of veterinary hygiene we might soon obtain a great school of general or comparative pathology serviceable alike to the state, the community, and the individual. Many preventable diseases would be abolished, stock-owners would become more prosperous, and the average life of man would be still further prolonged."

LONDON SCHOOL OF MEDICINE FOR WOMEN.

INTRODUCTORY ADDRESS BY MR. J. GROSVENOR MACKINLAY, F.R.C.S. EDIN.,
SENIOR OPHTHALMIC SURGEON, ROYAL FREE HOSPITAL.

Mr. J. Grosvenor Mackinlay, in delivering the inaugural address at the opening of the winter session of the London School of Medicine for Women, disclaimed any intention of giving a formal lecture on the advance made in surgery, medicine, and therapeutics during the last few years. He merely wished to make some practical remarks based on his own experience. In speaking of the origin of the medical movement amongst women Mr. Mackinlay traced its growth and accumulative strength through the troublous times of its initial stages, to the recent rebuff met with at Cambridge, and the refusal of the Royal College of Surgeons of England to grant diplomas to the sex. He characterised such policy as short-sighted, and the fees were in consequence being diverted into the more liberal spirited academies and colleges of Scotland and Ireland, Belgium and Sweden, or Paris. His hearers should show the authorities what they can do without their help and by the aid of Newnham and Girton. In alluding to women's medical work in Her Majesty's vast dominions particular stress was laid by Mr. Mackinlay on that carried on in our Indian provinces, the paramount requisite for pursuing this being good health. He felt that he might speak with some authority on the great need for female practitioners in the East, since both his father and an uncle had spent several years in the Indian Medical Service; and here he characterised as derogatory to the profession those women who obtain but a few months' training at a hospital or dispensary and return to the East with scanty qualifications, small knowledge, a Bible, and a few instruments, posing as "lady doctors," but in reality merely taking the bread out of the mouths of the more competent and properly qualified women. Woman has now released herself from the old bonds, especially by her entrance into the medical profession, with all its attendant responsibilities. Many of the studies have to be carried out under objectionable, but unavoidable, circumstances; none the less, woman's advance in the profession has been sure if slow. Recalling the meeting at Nottingham, at which qualified ladies were elected members of the British Medical Association, Mr. Mackinlay paid a tribute to the lifelong work of Mrs. Garrett Anderson and Mrs. Scharlieb, mentioning also that past gynæcological authority, Madame Boivin. The late Albert Smith called medical students "an interesting race," although in his time no women medical students existed; his advice to them was, "Forget the deeper studies, and forget the red globules of the blood in billiard balls." Ladies could substitute cycling, tennis, or other exercises for the billiards. Considering the many eminent men connected with the Royal Free Hospital, the names of Mr. Wakley, Mr. Gant, and Mr. Rose immediately presented themselves. The speaker also dwelt upon the many changes in the building and in the *personnel* of the institution in the Gray's Inn-road, and alluded to the Hospital for Women and to the alterations now proceeding at the school in Handel-street. Of his own speciality—ophthalmology—Mr. Mackinlay treated very briefly, touching upon the far-reaching responsibility of the mode

Digitized by Google

of procedure in eye diseases and of the terrible deprivation which loss of sight meant to the uneducated poor. In this branch of the medical art, nerve, cheerfulness, and kindness were the essential weapons for the fighting of the hard battle against optical derangements. Amongst the advice tendered by the speaker to the students present was that of being just to their colleagues and to brother or sister practitioners, of the necessity for truthfulness and lucidity in dealing with patients and their relatives, and the positive need of dogged perseverance in the work. Despatch and method were the soul of the profession, and the smallest detail of deportment, whether of voice or of expression, required to be studied. The demonstration of sympathy should never be repressed, and none having a heart should simulate indifference, this latter being the perfection of selfishness. In conclusion, the lecturer spoke in warm terms of appreciation of Lord Lister, and as a corollary suggested that Her Majesty might institute some order of distinction for the women members of the medical faculty. Verily did they merit it since many of them had to go through not only serious trials but often through imminent danger, possibly unrecorded and sometimes unrecognised, and for these there had, so far, been no especial reward. Many women had died at their posts from cholera, diphtheria, fever, and other forms of contagious disease. They could only hope that the day was not far distant when a "Red Badge of Courage" would be instituted for medical women, as well as for women nurses, and that the Queen would see her way to further ennobling them. At any rate, even if all could not attain to the dignity of a great doctor at least duty might be fearlessly and thoroughly performed which would ensure contentment. With Hazlitt all might then say when their time was over "Well, I have had a happy life."

SPORADIC CRETINISM.[1]

BY A. GORDON PATERSON, M.A., M.D. EDIN.

IT is now an accepted fact, I think, that sporadic cretinism is a disease, probably congenital, occurring in infants and children, analogous to, if not identical with, the disease of adult life termed myxœdema. In both the essential feature is either the absence or the deficient action of the thyroid gland. Curling was the first who, in 1850, drew attention to the fact that in cretins the gland was either absent or diseased. Hilton Fagge later stated what he considered would be the condition of an adult in whom the thyroid gland ceased to perform its functions—that is, he drew a correct clinical picture of myxœdema. If we allow for the fact that in infants and children the whole system, and especially the brain and bones, is undergoing rapid development and that in adults these processes have come to an end we shall find that we have to deal with a disease which is identical in both. In each disease the cerebral, motor, and trophic nervous systems are profoundly affected. In the infantile form the disease is probably due to some intra-uterine condition of either absence or mal-development of the thyroid gland. There are two theories propounded in regard to the reason why an absent or deficient thyroid gland should give rise to these abnormal conditions. The first is that the gland secretes some substance which is essential to the healthy and harmonious working of the central and peripheral nervous systems. By the want of this substance the nervous mechanism is deprived of a something which regulates the formation and deposition of mucin products, so essential a feature of both diseases, the mucin being thus deposited in the superficial and finer meshes of the corium, impairing motility and impeding nervous impulses, afferent as well as efferent. The second theory is that the thyroid gland excretes from the blood some materials formed in the body metabolism which by their retention cause a form of toxæmia, affecting principally the cerebral centres and the nervous mechanism concerned in mucin metabolism. Whichever theory may prove correct, the result is the same—viz., the production of some substance which counteracts the abnormal constituents of the blood. This is clearly shown by the rapidity with which the œdema disappears under treatment, and shows that the substance has a solvent action on mucin when deposited, and therefore in health acts on the mucin constituents, which, if left to pass freely through the body, become deposited as mucin. The thyroid gland being ductless rather points to a secretion than an excretion. Otherwise, how are we to account for the fact that implanting thyroid gland in the body causes an improvement? There cannot in such cases be an excretion, but rather a secretion of some substance neutralising the toxic materials in the blood and system. When the disease occurs in early childhood it is probably due to the gradual failure of an imperfectly formed thyroid gland. When the disease occurs in adults the cause is usually some abnormal condition of the gland which, though acting imperfectly, finally ceases to perform its functions. That the secretion of the thyroid gland exercises a powerful effect on the animal economy is evident if the results are noted when the extract of the gland is administered in myxœdema and in cases of obesity. The marked thinning that occurs by the removal of the œdema is palpable to the most casual observer. What the causes are which lead to the mal-development of the gland is not known. It has been suggested that cretinism might be due to what has been termed alcoholic conception. From the history of this case and of another which unfortunately died before treatment could be commenced the alcoholic factor must certainly be left out of account. Before I pass on to detail the case of the child I would like to say that it is interesting from three points of view. Firstly, the early age at which the disease commenced, the immediate and remarkable effects of the thyroid treatment, and the steady improvement which has been maintained to the present time—a period of treatment lasting for five years. Secondly, the fact that the mother gave birth in December, 1893, to a second (female) child, which was an exaggerated counterpart of the first and which only survived its birth twenty minutes. Thirdly, the very interesting fact that the mother in her third pregnancy was treated by thyroid extract from the beginning of the third month and gave birth in October, 1896, to a fine healthy female child. I shall now pass on to the case.

Infant treated with thyroid extract from the nineteenth month to the sixth year.—A male child was first brought to me, when eleven months old, the mother stating that from the seventh month it was noticed that he was backward and suffered from obstinate constipation, which did not yield to the ordinary simple remedies. As, however, the child had been bottle-fed from the seventh month it was thought possible that the constipation might be due to some error in the food. It was also further noticed that the fontanelles were very open and that the child was always cold. The mother said that the labour was the first, with no previous miscarriages, and was easy but slow, lasting twenty-three hours, there being no liquor amnii. The family history did not disclose any facts which in the least offered a clue to the disease. There was no consanguinity between the parents, nor was there any trace of disease associated with thyroid fault or syphilis. The mother was a healthy young woman, twenty-eight years of age, active and sober. The father was a tolerably healthy young man, twenty-nine years of age, of a pale complexion and black hair. He suffered occasionally from headaches and bilousness, which he attributed to want of exercise. He suffered from cold hands and feet. He was sober. When thirteen years old he had a diseased hip, but was treated for a broken leg till it was found out and put right. The only sign of the diseased hip is a slight shortening of the left leg. I was unable when I first saw the case to get photographs of the child. Those here reproduced were taken at the age of nineteen months, when the condition was practically the same as at eleven months. (See Figs. 1, 2, 3, and 4.) In the interval between the eleventh and nineteenth months the treatment was directed in trying to overcome the obstinate constipation, but without success. The illustrations bring out very well most of the details which I shall now describe. There were no signs of teething, he had never had diarrhœa, febrile attacks, or convulsions. His height was twenty-five inches; the head was large and dolichocephalic (Fig. 3); the anterior fontanelle was very open and the frontal suture distinct, the occipito-parietal junctions were widely separated, and on the right side there was a triangular space devoid of bone. The hair, which was brown with a reddish tint here and there, was scanty, fine, and short, the scalp was covered with a branny scurf, the face was of a dirty-yellow colour, but there was no

[1] A paper read before the Reading Pathological Society on April 15th, 1897.

Digitized by Google

blush either on the cheeks or nose. There was occasionally ciliary blepharitis. The nose was a short pug, very flat and broad at the root, and the cheeks were thick and pale. The mouth was widely open (Fig. 1) and the tongue, which was very large — too large, in fact, for the mouth,—always protruding. The ears were moderate in size, but waxy. The neck was thick and short, but the sterno-thyroids were very distinct. No trace of a thyroid gland could be made out, but there was a slight swelling

FIG. 1.

Infant, aged nineteen months, showing protruding tongue.

over the right clavicle. There were no lipomata anywhere else. The abdomen was barrel-shaped and very tense (Fig. 2), and the superficial veins were very distinct. The whole body was bluish and mottled. There was a small umbilical hernia the size of a hazel nut. The limbs were hard, swollen, and lumpy, very cold, and purple. The mottling was most distinct from the elbows to the finger tips and from the knees to the toes. The hands were remarkably thick and hard from the solid œdema, which did not pit at all. There was a slight anterior curvature of the spine, but no signs indicative of rickets were present. There were no fatty or hairy growths between the scapulæ (Fig. 4). The skin was always dry and harsh, but there were no moles, warts, nævi, eczema, or ichthyosis. The secretion of sweat was almost entirely absent, saliva was abundant, but the nasal secretion was wanting. The muscular development was apparently extremely limited, as shown by the complete immobility of the limbs, but this was evidently due to the solid œdema preventing free action, for it rapidly disappeared on the removal of the œdema under treatment. The reflexes were normal as far as I could judge, the skin sensibility was fair, and sight and hearing were normal. The left testicle had descended into the scrotum, but the right one was still in the inguinal canal. This fact seems to negative the theory that the condition is primarily due to non-development of the sexual organs. The rectal temperature was 97·2° F. The child was extremely susceptible to cold and liked to be always near the fire The voice was harsh and blanketty. As regards mental development spontaneity was entirely absent, this being also probably greatly due to the œdema of the limbs. Intelligence was *nil*. Sleep was variable. There was great anæmia, but the appetite was good. The bowels, as already stated, were very constipated and the actions were putty-like. The liver and spleen were apparently not enlarged. The urine was clear, straw-coloured, and normal. The heart was normal, but the pulse was very feeble. The respiration was regular, but noisy, owing to the size of the tongue. There were no enlarged glands anywhere. Such were the typical signs of the disease at the age of eleven months. The only differences noted at nineteen months, when the photographs were taken—a period of seven months, during which no thyroid extract was given—were as follows. The anterior fontanelle was still very open, but the left parieto-occipital junction had closed up, and in the right a Wormian bone could be felt; all the sutures were closing up. There were still no signs of teething, and the hair was more abundant. The redness and veins of the eyelids had disappeared, as had also most of the veins of the abdomen. The abdominal mottling and tenseness were less—results due, I believe, to the fact that the child's circulation was better, owing to warm clothing and precautions against cold. The umbilical hernia was smaller, muscular action was better, but he could not sit up at all even with help and could only just move his limbs. He could still only drink while lying down, as owing to the size of the tongue the fluid escaped if he was placed in a sitting posture. The rectal temperature was 96°, and that in the groin was 95 8°. It will thus be seen that during seven months his condition had remained practically *in statu quo*. The thyroid extract was now commenced and consisted in the administration of seven drops of the glycerine extract prepared by Messrs. Brady and Martin, of Newcastle-on-Tyne. After the third dose the face appeared to be smaller, the tongue was perceptibly more in the mouth, and the hands were softer and showed fine creasing and wrinkles due to the removal of the œdema. Spontaneous action was greater, as shown by his rubbing his eyes and trying to grasp objects held up to him, this increased motility being undoubtedly due to the softening of the limbs. After the fourth dose he developed a coryza, and the extract was stopped, but, symptoms of bronchitis threatening, the extract

FIG. 2.

The same, showing umbilical hernia.

was again resumed, with the remarkable result that next day all the coryza and febrile symptoms had disappeared. After the sixth dose the tongue, though still very large, was wholly within the mouth and the pharynx could be seen; this had previously been quite impossible. The next remarkable point is that the bowels now became quite regular and the actions normal in appearance. The urine was not in any

Digitized by Google

way affected. The most marked feature, however, with the exception of the diminution in the size of the tongue, was that the child had lost the feeling of coldness and no longer became cold when left alone in his crib; in fact, his

FIG. 3.

The same, showing shape of head.

temperature was always from this time practically normal. At the end of a week his limbs had become quite soft and pliable, and he could even sit up in his perambulator with a little help, and when put on the floor made attempts at crawling. At the end of a month's treatment he showed

FIG. 4.

The same, showing position in sitting.

signs of eight teeth and his colour had become natural. This rapid improvement during the first month or so of treatment has also been noticed in most of the published cases. The patient's condition at the end of five months' treatment

FIG. 5.

Showing condition after five months' treatment.

is well shown in Fig. 5. The anterior fontanelle was still unclosed. At the end of eight months' treatment, during which time he had continued steadily to improve, he had cut sixteen teeth, and his general appearance is shown in Fig. 6. The extract was now omitted and the child was fed on fresh

FIG. 6.

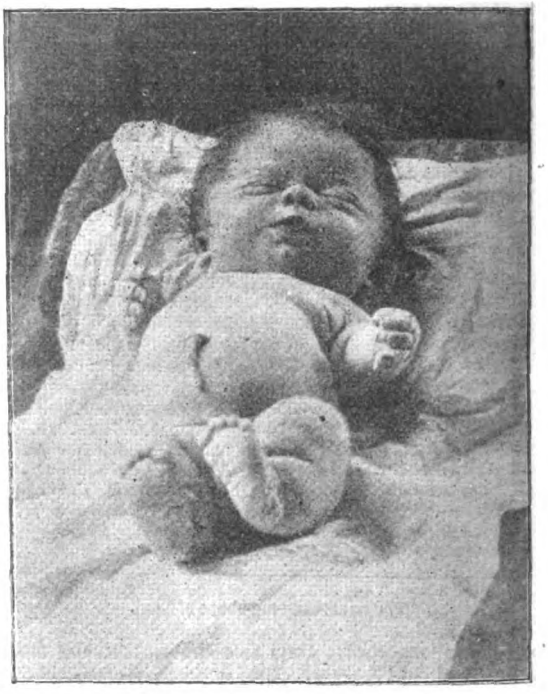
Digitized by Google

sheep's thyroid, half a gland being given once a day; this he continued to take till the end of 1895, when, owing to his not showing signs of talking, I returned once more to thyroid extract, this time in the form of tabloids (five grains), prepared by Messrs. Burroughs, Wellcome, and Co., one a day being given. Very soon he showed more progress in trying to make himself understood by words, and he could always, if he wished, repeat words said to him, but he did not seem to have the power of saying spontaneously any but the most simple words, and these chiefly connected with eating or playthings. He has always had a most acute ear for music and constantly asks his father to play the accordion. One word he had always said spontaneously was "doctor." From the commencement of this year his mental development has increased greatly, and he is now able to repeat consecutively part of his ABC and can name the various objects in his picture-books, but he cannot yet speak a connected sentence. His height is now 40½ in., his weight 44 lb. This weight for height corresponds to the average in the tables. His appearance is well shown in Fig. 7, taken on March 25th of this year. It will be seen that he presents

FIG. 7.



Showing condition at the age of five years and nine months.

little appearance or traces of his former cretinoid condition. It will be interesting to watch to what point of mental development he will attain.

Infant, also a cretin; died twenty minutes after birth.—The next point of interest is that in December, 1893, the mother of the patient in Case 1 gave birth to a female child, who only survived her birth twenty minutes and who was an exaggerated counterpart of the first. The appearance of the child is shown in Fig. 8, taken the day after birth. The labour was easy and the amount of liquor amnii was enormous. The presentation was a breech, somewhat puzzling from the fact that the feet seemed to spring from the hips, owing to the extreme shortness and thickness of the legs (Fig. 8). The body was very large and solid from œdema, which did not pit anywhere. The weight was 10 lb. 14 oz. The placenta was very small, and the membranes were tough and gelatinous. The frontal protuberances were very prominent, the bones of the head were soft and widely separated, and the left parieto-occipital junction was deficient in bone to a large extent. The circumference of the head was sixteen inches. The hair was very thick, long, and fine, and reached to the eyebrows as a thick down; it was also very thick and dark over the spine scapulæ, thighs, and buttocks. The colour of the skin was a dirty-yellow, the abdomen was barrel-shaped, the limbs were very short, hard and brawny with deeply marked sulci in the fingers and limbs (see Fig. 8). The

FIG. 8.

Second child, survived only twenty minutes.

length of the arm from the acromion process to the tip of the middle finger was 6½ in., the length of leg from the hip to the sole of the foot was 7 in., and the height from the vertex to the sole of the foot was 16 in. The circumference of the thorax was 11½ in., and of the abdomen at the umbilicus 14 in. I was, unfortunately, unable to make a post-mortem examination.

Mother treated with thyroid extract from the third month of pregnancy; birth of healthy child.—I now come to the most interesting part of the case—viz., the treatment of the mother in her third pregnancy, from the beginning of the third month, by thyroid extract in the form of tabloids, prepared by Messrs. Burroughs, Wellcome, and Co. The fact of the mother having given birth to two cretins in successive pregnancies offered a strong presumption that she would, unless treated, give birth to a third. I therefore pointed out to her, that, while I could not promise success, I felt confident that if she persevered in taking the tabloids regularly during the whole time of her pregnancy, she would in due course give birth to a healthy child. As she was agreeable to this proposition, I advised her to take one tabloid every day during the remaining seven months of the pregnancy. This she did. At no time did she suffer from any discomfort, but on the contrary was much better throughout than she had been in the previous pregnancies. The only effect the tabloids seemed to have was that of fining her down and making her somewhat thinner. Labour came on naturally at full term and was easy. The liquor amnii was not unusual in quantity or appearance. The placenta and membranes were quite natural. The child was a fine healthy female, indistinguishable from any other infant in appearance. The height was 22 in. and the weight 8½ lb. Unfortunately the photograph I took at the time was destroyed, and I have, therefore, only two

Digitized by Google

photographs in my possession to show the child at the age of five months. From one of these (Fig. 9), I think it will be admitted that the infant is a remarkably fine and intelligent little creature. She is very bright and intelligent and can sit up firmly, shows signs of teething, and can say "da-da." She has so far had no ailment of any sort. Her height is now 26 in. and her weight 19 lb. 6 oz. I am satisfied that treatment of the mother was the cause of the child being born healthy. At the same time,

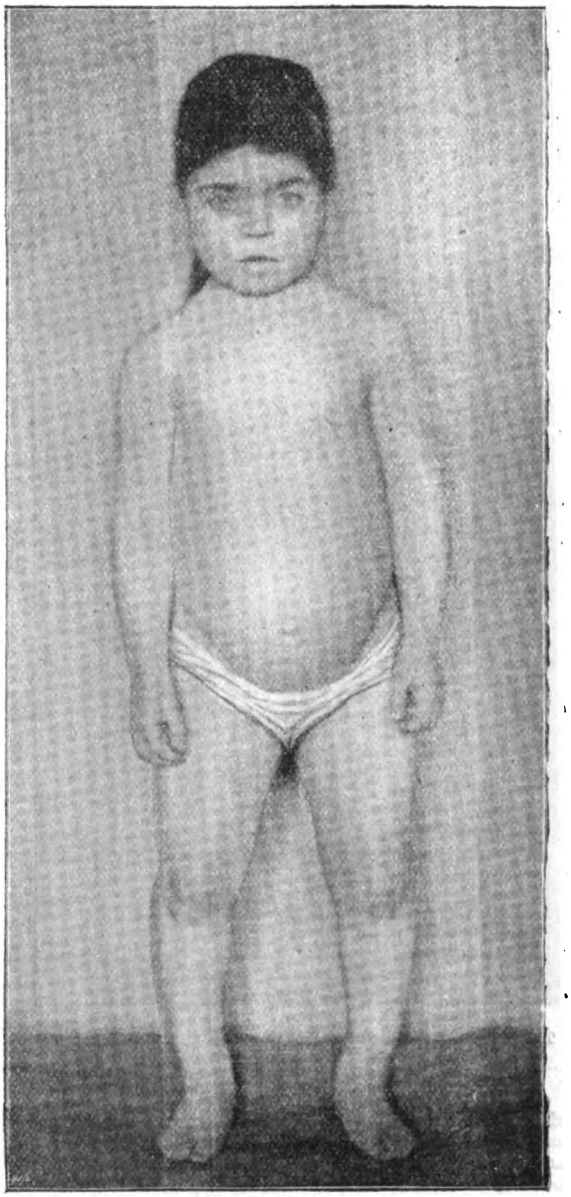
FIG. 9.

Infant, aged five months, born after administration of thyroid extract to the mother during pregnancy.

I am aware of the possible objection that it is a case of "Post hoc ergo propter hoc." Seeing, however, that the mother has resided here all the time, the statement that a mother who has borne cretinoid children may bear a healthy one by residing during her pregnancy in another place will not hold as an objection in this case, and we must fall back on the alternative that the birth of the healthy child was altogether due to the administration of the thyroid extract. I am not aware of any records of thyroid treatment continued for the same length of time, regularly, in the same child, or of the treatment of a pregnant woman who had borne two previous cretin children giving rise to a healthy child being produced. I therefore think that the case will prove interesting to the medical profession.

P.S.—The boy continues to show a marked improvement in his mental development, and displays a considerable amount of spontaneity in his conversation. He is now six years and three months old. The infant (Fig. 9) is, to all outward appearance, in every way a thoroughly healthy baby and well advanced for her age. She is able to stand and to say several words. She is now eleven months old.

Ascot.



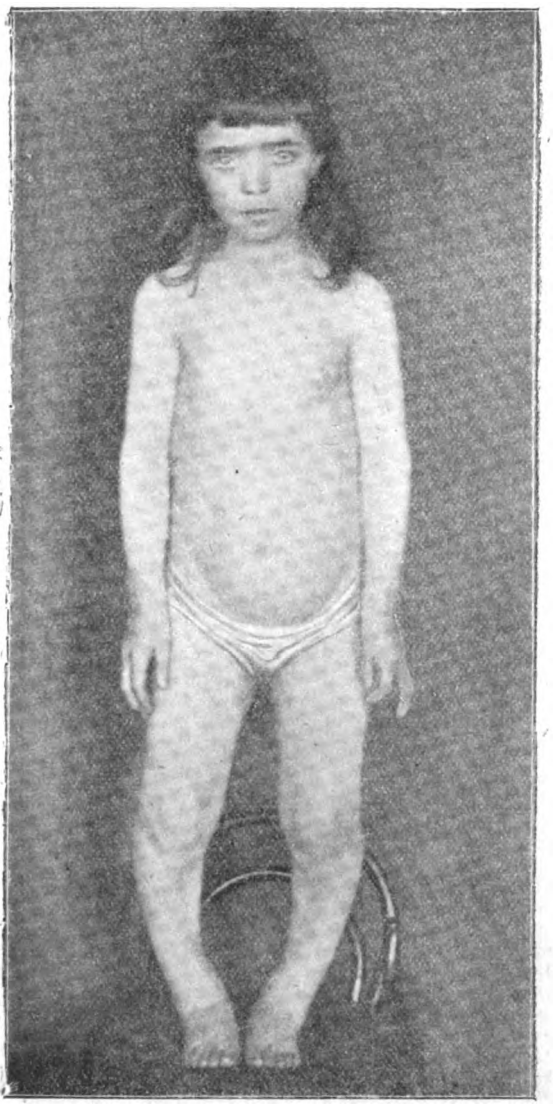
THE BRITISH ASSOCIATION.—The local committee who are making the necessary arrangements for the visit of the British Association to Bristol next year held a meeting on Sept. 21st. Professor Lloyd Morgan stated that he had conveyed the invitation of Bristol to the Canadians and to members of the American Association. The committee recommended Sept. 7th and following days as the most convenient date for the meeting to be held. This date will be finally determined at the meeting of the General Committee of the association to take place in London on Nov. 5th, when the president for the coming year will be elected.

TENDENCY TO BENDING OF THE BONES IN CRETINS UNDER THYROID TREATMENT.

BY T. TELFORD-SMITH, M.A., M.D. DUB.,
MEDICAL SUPERINTENDENT, ROYAL ALBERT ASYLUM, LANCASTER.

ONE of the most marked among the many other signs of development produced in cretins during the administration of thyroid preparations is the rapid increase of growth in stature which takes place—an effect which is all the more striking when we remember that in these cases growth is almost at a standstill previously to treatment. The boy, notes of whose case I published in 1894,[1] grew four and a quarter inches in ten months under thyroid treatment, and his

FIG. 1.



The patient at the age of fifteen and a half years (before treatment). Height, 3 ft. 6 in.; weight, 4 st. 2 lb.

Digitized by Google

brother grew four inches in less than a year under similar treatment, as recorded by Dr. T. C. Railton.[2] As a point in the practical treatment of these cases I have found that during thyroid treatment this rapid growth of the skeleton leads to a softened condition of the bones, resulting in a yielding and bending of those which have to bear weight; and as cretins under treatment become much more active and inclined to run about this tendency to bending has to be guarded against. The girl, aged seventeen and three-quarter years, of whom photographs are reproduced, shows this increased bending of the legs very well. She has now been continuously under thyroid treatment for two and a quarter years, taking one five-grain tabloid (B. and W.) daily with her dinner, and

FIG. 2.

The patient at the age of seventeen years and nine months (after two and a quarter years' thyroid treatment). Height, 4 ft. 1½ in.; weight, 4 st. 10½ lb. Showing increased bowing of legs and enlargement of knees and ankles.

during that period she has grown seven and a half inches (from 3 ft. 6 in. to 4 ft. 1½ in.). During the period of two years previous to treatment she had only grown an inch[3] (from 3 ft. 5 in. to 3 ft. 6 in.). (Fig. 1.) For the last few months she has been kept as far as possible at rest, so as to prevent, to some degree, this bending of the legs. The second photograph shows that the bending takes place most markedly in the tibia and fibula, the increased size of the ends of these bones at the ankle and knee being very noticeable. Several of the photographs of cretins before and after thyroid treatment exhibited by Dr. W. R. Parker, of Kendal, and Dr. John Thomson, of Edinburgh, at the meeting of the British Medical Association at Carlisle, showed this increased bending of the legs very clearly, and the condition was remarked upon and discussed. Mr. Victor Horsley showing in this connexion slides to illustrate rickets produced in rabbits by Hoffmeister, and in sheep and goats by von Eisenburg, by removal of the thyroid gland.

While in rickets, however produced, there is perverted and delayed ossification resulting in softening and bending of the bones, under thyroid treatment in cretinism there is rapid resumption of growth in the skeleton, leading to softening, which is most marked in the long bones and at the epiphyses. Cretins under thyroid treatment should, therefore, be watched for any commencing bending of the bones of the legs, and if such appears the child should for a time be hindered from walking or the legs supported by light splints. As an additional means of assisting the rapid bone and other growth the diet should be generous and the child should get plenty of sunlight and open air. The administration of cod-liver oil and Parrish's food would probably prove beneficial at the same time.

[3] Cases of Sporadic Cretinism Treated by Thyroid Extract, by Dr. T. Telford-Smith, Journal of Mental Science, April, 1896.

A CASE OF ADVANCED CRETINISM TREATED BY THYROID EXTRACT.

BY H. E. DRAKE-BROCKMAN, F.R.C.S. EDIN.,
SURGEON-CAPTAIN, INDIAN MEDICAL SERVICE.

AT the present time, when the treatment of certain diseases by the administration of thyroid extract is more or less *sub judice*, the following case of a marked cretin which came under my care and was subjected to this treatment may prove of interest to the profession.

A boy, caste Dhobi, was one day brought to me by his father for examination suspected of being an idiot. A cursory inspection of the youth was sufficient to reveal his true condition—viz., that of a marked cretin. It appeared on inquiry from his parents that the disease first showed itself in the lad about six years before in the shape of deafness, followed by dulness of intellect, slowness in perception of things said to him, dilatoriness in movement, coupled with a want of coördination, which ultimately developed into the usual waddling gait. At the first inspection he presented more or less all the typical symptoms of a cretin, in that he had the usual heavy, dull expression of countenance, the mouth half open, with saliva dribbling over the chin, the tongue protruding between the teeth, the eyelids puffy, with a very platyrrhine nose and brachycephalic head; his figure was squatty, but not much deformed. There was slight tendency to exophthalmos, the thyroid was distinctly enlarged, and the superficial skin covered with distended veins, more so to the right side, where the tumour was markedly tense and somewhat elastic to the touch, rather suggestive of the presence of cystic growth. Over the point of most prominence on auscultation there was a marked bruit, slightly musical in character. Measurement of the neck round the tumour accurately taken showed the circumference to be 14⅜ in. The heart sounds were normal, and so were those of the lungs, with the exception of slight stridor noticeable over the enlarged thyroid, owing probably to pressure of the growth on the trachea. The urine was also analysed and was found to be of specific gravity 1025, reaction acid, and contained neither albumin nor sugar. Towards the end of November last the thyroid treatment was begun by administration of three grains of the dry extract by the mouth daily. After the lapse of one month the boy was again thoroughly examined and the following note was made by me at the time: "The boy's whole appearance has improved most markedly, his sense of hearing and perception of things said to and around him is much acuter, the eyelids are much less puffy, and his gait has also lost some of its waddling character; he has

Digitized by Google

been able to walk four miles daily for the last week. The thyroid enlargement also was carefully measured by me to-day in the exact spot as before and was found to be 12⅜ in.; the tumour itself has become much softer, and the bruit mentioned above has very nearly disappeared." It will be seen from the note taken that the thyroid enlargement had diminished fully 2 in. since the commencement of the treatment—that is, in the space of one month the gland had markedly atrophied—and the general condition of the lad, both physically and mentally, has shown marked improvement. Seeing that the treatment had acted so beneficially I decided to increase the dose to five grains daily, which was accordingly done. A whole month was allowed to elapse from this date, the lad being under daily observation as before and the medicine daily administered. At the end of the month—that is, two from the date of the commencement of the treatment—a thorough examination of the boy was again made, and the following note was registered: "The bodily condition of the patient has again showed steady improvement, his hearing and intellect are much improved, the boy can run now, and has hardly anything left of the waddling gait. The measurement of the tumour was again taken to-day and found to be only 12 in. and the neck of the patient has assumed a more or less normal aspect; there is no bruit audible at all in the spot previously noticed. The marked and steady improvement registered in the last note still continues." The treatment, as above indicated, was continued without stopping daily for another month, at the end of which a still further improvement was noted in every respect, the boy could at once interpret what was said to him and reply to it in an audible voice, and with clearness too. At this examination I noticed a marked absence of patellar reflex, this being a prominent symptom in tabes dorsalis, in which it had been stated by the late Professor Brown-Séquard that orchitic fluid had worked wonders. I decided to try the effect of it in this case, and so administered to him five grains of didymin daily as well as the thyroid extract. After the lapse of a fortnight there were signs of the reflex returning, he certainly became much stronger on his legs, and could run if desired; he latterly used to walk about eight miles daily to come to see me, when, to my regret, having to leave the district on transfer to another station, I have in consequence lost sight of the lad, and thus a most interesting inquiry has been unavoidably and abruptly terminated. I took the opportunity of obtaining a sample of the water usually consumed by the patient and his family and sent it for analysis to the chemical examiner, who found that the water contained 44·8 grains per gallon of total solids, the greater portion of which was lime salts. There is not much information to be gained by the family history of the patient, which is briefly as follows. The father is alive and free from any disease, as I have had ample opportunities of verifying for myself. The mother died years ago, and used to suffer from what is described as epilepsy. There is no history of syphilis; there are two children, both males, the elder a youth of about nineteen years of age, and perfectly healthy, whom I have also seen for myself; the younger son (this patient) a lad of about sixteen years old, who is a marked cretin. It is interesting to note that the boy's home is at the foot of the hills in a kind of country in which cretins are usually expected to be found, and I hear, on inquiry, though I have not been able to verify it, that there are a few in the neighbourhood.

Since the above case I have come across one somewhat similar, treated and reported by Dr. Rushton Parker, of Kendal, quite independently of and unknown to me, which I have read with great interest, though the two cases differed somewhat materially in many little ways, as will be seen on reference to them; both cases, however, improved so wonderfully under this treatment that it gives one great hopes that something more than temporary relief may be ensured by it. The case above narrated has a great many points of interest attached to it, in that it was an advanced one, not only in years, but in severity of its symptoms, the rapid diminution, which I presume was simple atrophy of the thyroid tumour after the administration of the drug, also the rapid and marked improvement which took place in both the patient's mental and physical condition, notwithstanding the comparatively short time that he was subjected to the thyroid treatment. Though I am fully aware that the case is more or less incomplete, still the benefits derived by the patient at my hands under this treatment in so short a period afford me sufficient excuse for bringing this case to the notice of the profession, in the hope that others who have greater facilities than myself for treating the disease may be induced to give it a fair trial and record their experiences.[1]

Bengal.

NOTES ON A CASE OF CRETINISM SUCCESSFULLY TREATED WITH THYROIDIN.

BY C. MORTON ANDERSON, M.R.C.S. ENG.

IN the early part of 1893 I had read with much interest the accounts published in the English medical journals of several cases of cretinism which had been successfully treated by the administration of the thyroid gland of the sheep or of some of the many preparations which were being made from that gland. In the latter part of that year I had an opportunity through the kindness of Dr. Ord and others of seeing many of those patients whom I had previously been reading about, as well as several others, and of judging of the results for myself. I was very much impressed with what I saw, the change for the better in many of the patients being marvellous; but I do not remember seeing one, especially in so old a child, in which the result of treatment was more striking than in the case related in the following notes. The accompanying illustrations from photographs, though very imperfect (being my first attempt at photography), will perhaps show better than words the physical condition of the patient before and after treatment.

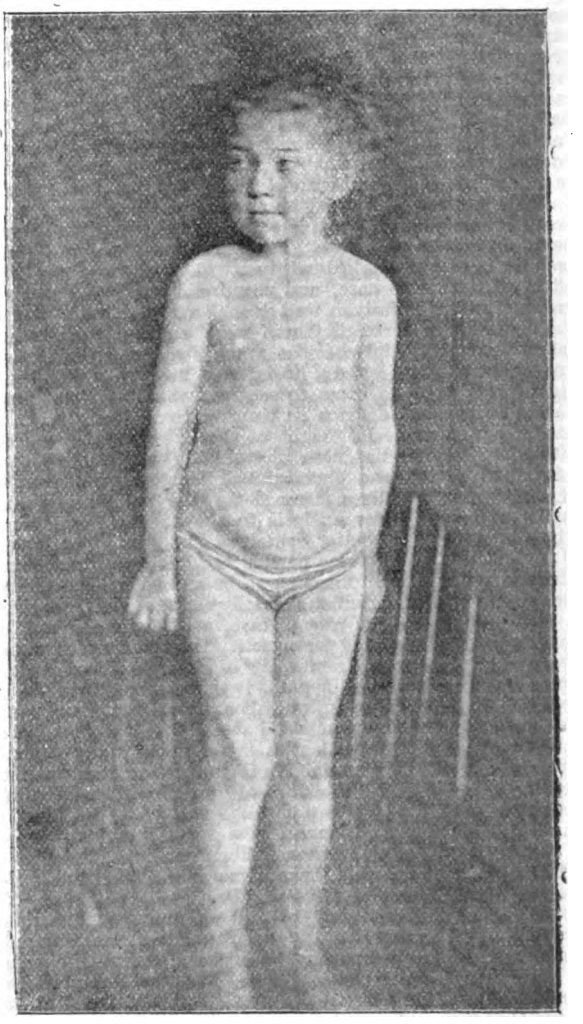
The patient, a girl aged eleven years, first showed symptoms of cretinism when about three years of age. She had been under professional treatment in various ways previously, but with no good result. Early in 1893 I had put her on a strict dietary for nearly three months but with very little benefit, and on Jan. 1st, 1894, she weighed 4 st. 7 lb. in her ordinary clothes, and measured 3 ft. 4½ in. in height, a gain of three-quarters of an inch having been made during the previous year. This gain, though small, had been the greatest she had made for some years. On Jan. 16th, 1894, her features were thick and blunted and she was excessively corpulent. There were large supra-clavicular folds of fat and there was a large hump of the same substance over the lower cervical and upper dorsal vertebræ. She felt like a dead weight when lifted, and the skin, which was cold to the touch, felt harsh and dry. Her hair was long and thick; her appetite was poor, but the bowels were fairly regular and she slept well. The child's intelligence was decidedly dulled and slow, and there was great want of animation; she drawled her words and spoke slowly and in a deep, peculiar voice. She had been at school for a year and a half but could only spell a few monosyllables or add up three or four figures. The circumference of the chest was 24½ in. and of the abdomen 27½ in. (See Fig. 1, which was taken at this time.) The pulse was 60. I ordered 2½ gr. of thyroidin to be given every second day, which I increased to 5 gr. on Jan. 23rd. On Feb. 2nd the temperature was 98·6° F., and the pulse 78. She was much brighter and more animated. The clavicular folds and the cervical hump were decidedly softer and rather smaller. The digestive functions were not in the least disturbed and the appetite had improved. I ordered one 5-gr. tablet daily. On Feb. 23rd the patient weighed 4st. 11lb. The temperature was normal, the pulse 100, and the skin moist and supple. She was very much sharper and more animated and cheerful, becoming quite hilarious and playful. The abdomen was not nearly so large and the clavicular folds were fast disappearing, but the cervical hump looked quite as prominent. I ordered a 5-gr. tablet to be given each morning and half a tablet each afternoon. On March 14th the patient's height was 3 ft. 5 in. and her weight 3 st. 12½ lb., being a gain of half an inch in height and a loss of 8½ lb. in weight in two months. The child sometimes seemed rather pale and weak. She was ordered to take only one tablet daily. On the 21st the patient seemed better and was ordered to resume taking one and a half tablets daily. On April 20th her height was 3 ft. 6 in.

[1] We regret that the photographs sent by Surgeon-Captain Drake-Brockman to illustrate the good progress of this case were not suitable for reproduction, but the notes tell the story perfectly clearly without them.—ED. L.

Digitized by Google

and her weight barely 3 st. 10 lb. The clavicular folds had quite disappeared, the cervical hump was almost gone, and the spines of the vertebræ could easily be felt through it The abdomen was nearly normal in shape. The patient was quite bright, animated, and natural, but inclined to be thin. One tablet every second day was now ordered. On Aug. 11th her height was 3 ft. 7½ in., her weight being 3 st. 13 lb.—a

FIG. 1.



Before treatment.

gain of 3 in. in height and a loss of 8 lb. in weight in a little less than seven months. The temperature and pulse were normal, the skin was fresh and healthy, the appetite very good, and the bowels regular. She never had bilious attacks now, though she was formerly very subject to them. On Nov. 15th the patient's general health was good and the skin and complexion were quite natural. The cervical hump had quite disappeared, the back in that region being like that of an ordinary child. She had grown 1½ in. in the last three months and had lost ½ lb. in weight. For the last three weeks she had only been taking half a tablet daily. The dose was now reduced to one-third of a tablet. On March 1st, 1895, the patient was in perfect health and in good spirits and quite as sharp and intelligent as any child of her age and education should be. Although I considered her cured I advised her to continue to take one-third of a tablet daily, so as to guard against the possibility of a relapse. She had gained about 3 lb. in weight since November, and her height was 3 ft. 10½ in. It will be noticed that in the thirteen and a half months that had elapsed since the commencement of treatment (Jan. 16th, 1894) the child had grown exactly six inches in height, besides which all symptoms of cretinism had completely disappeared (see Fig. 2. which was taken at this time). On Aug. 24th her height was 3 ft. 11¾ in., and her weight 4 st. 8½ lb. She was still taking one-third of a tablet daily and was in perfect health, attending school regularly. Her schoolmistress had sent home a most excellent report for the term both as to the child's progress and as to her ability for learning. Up to January, 1896, the improvement had been permanent, though the rate of growth had dropped to about ¼ in. per month, which I consider ample. She was taking a quarter of a tablet daily now and often missed a dose.

There was no history of any symptoms like cretinism to be obtained in either her father's or her mother's families, nor could I get any history of goitre. Her mother had a cervical hump like the patient, though not so large in proportion, and there were no clavicular folds. She was not at all inclined to be stout till after her first three children were born, but afterwards she had developed an enormous amount of adipose tissue, more especially from her waist downwards. I tried dieting her carefully for some months, and afterwards I treated her with thyroidin for four months, but the result was *nil* so far as the obesity was concerned, and I found that the drug had a rather depressing effect. I should mention also that both parents are particularly sharp, bright, and intelligent. There are five other children in the

FIG 2

After treatment.

family, one older and four younger than the patient. All are bright, intelligent, and well-grown for their ages, but all are inclined to be rather stout as young children, though not so when they grow older.

Christchurch, New Zealand.

DEVIZES COTTAGE HOSPITAL. — The annual meeting of the subscribers to the Devizes Cottage Hospital was held on Sept. 23rd under the presidency of the Mayor. The report showed an increase in expenditure and a decrease in revenue. The medical staff were re-elected.

THE USE OF DECALCIFIED BONES IN THE TREATMENT OF WOUNDS.

BY F. W. ROBINSON, M.D. ABERD., M.R.C.S. ENG.,
HONORARY SURGEON TO THE HUDDERSFIELD INFIRMARY.

THE use of an animal dressing in the treatment of wounds was suggested in the method of "sponge-grafting," adopted, for a time by many surgeons. In principle this promised much success, but in practice it failed to realise what was anticipated from it. Professor Hamilton, who first introduced sponge-grafting to the profession, claimed for it the following advantages: (1) that, being porous, it imitated the interspaces of blood coagula and fibrinous lymph; (2) that, being an animal texture, it would be slowly absorbed; and (3) that, being pliable, it would easily adapt itself to the surface of wounds. In cases quoted by him and others granulation tissue was shown to grow into the pores of the sponge and osteoclasts were demonstrated as lying against the trabeculæ, which, however, were only very slowly absorbed. Sponge-grafts included in the peritoneal cavity became adherent to the intestine and showed the same tendency towards organisation, vascular granulation tissue growing into the grafts. These experiments are useful as showing that a dressing of animal tissue exerts a healthy influence upon wounds by stimulating, directing, and supporting the growth of their granulations; and there is no doubt that if sponge were more absorbable it would be a valuable dressing and would secure more general adoption. The absence of this quality is, however, fatal to its usefulness, and completely antagonises the many useful and necessary qualities it otherwise possesses. In order to be effective when applied to a wound an animal dressing ought to approach as nearly as possible to the conditions present in the physiological repair continually taking place in the living body. These latter differ from the processes occurring in a granulating wound inasmuch as absorption and repair are intimately correlated, and this natural affinity between the two should guide us in the selection of any dressing. In the ordinary mode of healing by granulations it is found that absorption is in a large measure lost; therefore the addition of an absorbable dressing of animal texture would seem, *par excellence*, to be the one thing necessary to fulfil the conditions required. The above considerations led me to try the effect of decalcified bones in the treatment of granulating wounds. For this purpose I used the most cancellous portions of the bones of an ox thoroughly depriving them of their fat, decalcifying and preserving them in a 1 in 20 solution of carbolic acid. Properly prepared the bone should be as soft as sponge, porous, and pliable. I have used the dressing in many cases and feel fully justified in recommending it. The impressions left upon my mind by the use of "decalcified bone dressing" may be summed up as follows: (*a*) it may be used for any kind of granulating wound and has been very successful in obstinate fistulæ and callous ulcers; (*b*) in no case has it caused the slightest irritation; on the contrary, any existing irritation has subsided on the use of the dressing and the temperature has fallen—this applies even to fistulæ which have been left five days without re-dressing; (*c*) it brings about a healthy state of the granulations, and the discharges from the wound diminish; and (*d*) the dressing is gradually absorbed, melting down at the base and sides. The rate of the absorption varies, but the healthier the granulations the more gradual the absorption, so that in the treatment of a wound the dressing requires to be re-applied less often in the later stages. Where the wound is unhealthy and the secretion of pus free the dressing is rapidly absorbed and may require changing daily, but in a more favourable condition it may be left for four or five days. I use the dressing in the following ways. For open ulcers I shape a piece to fit the cavity as nearly as possible, and pack up any deficiencies with small pieces. For superficial ulcers I shave off fine grafts until the surface is covered. For fistulæ I tear off small portions and pass them down until they are filled. In packing fistulæ I use a probe with a flat button-like end, as the ordinary probe is liable to pass through the material.

It would be impossible to give descriptions in detail of cases treated by this method, therefore I will only briefly allude to the following cases, which were very marked in their results. 1. Two abdominal fistulæ following laparotomy for pyo-salpinx had existed for fifteen weeks before the application of the dressing, the length of the fistulæ when they were first dressed being one and a half inches and two and a half inches respectively. They healed in a fortnight, one being dressed three times and the other four times. 2. An abdominal fistula following oöphorectomy had been present for one month. The fistula when first dressed was one and a half inches long, and it healed in seven days, being dressed twice. 3. A tuberculous fistula of the neck following removal of glands, about an inch long, healed in five days with only one dressing. 4. A callous ulcer over the right tibia in a patient suffering from Bright's disease was under treatment for two months without any effect. I then excised the edges of the ulcer and applied the dressing for the first time. A fortnight after the operation the ulcer had almost completely healed. Lastly, I would allude to the influence of the dressing on superficial ulcers when applied in the form of grafts. It acts in the same way as an epithelial graft, and in some instances the effect has been remarkable. In one case the whole surface was mapped out by fine blue lines of young epithelium after a first application.

I know that it is still too early to pronounce definitely upon the value of the dressing, as this can only be proved by the practice and experience of many.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum allorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

UNIVERSITY COLLEGE HOSPITAL.

A CASE OF DIPHTHERITIC CONJUNCTIVITIS.

(Under the care of Mr. PERCY FLEMMING.)

AN ill-nourished child, aged four months, was brought to the University College Hospital on Aug. 4th, 1897. No very clear history could be obtained. The child was said to have had "weak eyes" since birth, and on the day before he was brought to the hospital it was noticed that the right eye had become swollen. On examination it was seen that there was much swelling of the eyelids on the right side. On attempting to separate them they were found to be to some extent united by a tenacious and distinctly fibrinous exudation. On everting the lids they were felt to be very indurated and stiff, and their conjunctival surfaces were seen to be covered completely with a firm greyish membrane, marked here and there with small ecchymoses. This membrane could not be stripped off readily, but fragments could be removed without causing any bleeding. There was a small amount of discharge not purulent in character. The cornea was hazy, but not ulcerated. The left eye showed some conjunctivitis, but no membrane was present, the appearance of the eye suggesting a late stage of a purulent ophthalmia. There was a thick discharge from the nose. The general condition of the child was bad, vomiting and diarrhœa being present, and much albumin was found in the urine. The case was regarded as one of true diphtheritic conjunctivitis, and the patient was immediately admitted to the hospital. The eyes were ordered to be bathed frequently with quinine lotion (four grains to the ounce), and a solution of atropine was dropped in at intervals. The same local treatment was continued on the 5th, and on the afternoon of that day 4000 units of diphtheria antitoxin were injected. On the 6th it was obvious that the membrane on the conjunctiva was much less marked; the discharge was thin and serous, and the appearance of the cornea was unchanged, but the general condition of the child was certainly worse; the diarrhœa and vomiting were more frequent and severe. The same evening the discharge from the right eye was distinctly purulent. On

Digitized by Google

the 7th the local condition was markedly improved, as scarcely any membrane was left on the lids; where the membrane had separated the conjunctival surface had a worm-eaten appearance; the cornea was still hazy. At 5.30 P.M. on the 7th the child died rather suddenly, the vomiting having persisted and the diarrhœa having become worse, in spite of treatment. At the time of admission (Aug. 4th) cover-glass preparations were made and numerous diplococci were found, but no bacilli diphtheriæ. Some cultures taken immediately after admission showed typical diphtheria bacilli in abundance. A culture taken subsequently to the free use of the quinine lotion, but before the injection of the antitoxin, gave negative results, as did all later attempts at cultivation.

Remarks by Mr. FLEMMING.—There is, and has been, a good deal of difference of opinion with regard to membranous conjunctivitis. Most authorities, following von Graefe's original description,[1] divide the cases of membranous conjunctivitis into two groups, the first including cases of true diphtheritic inflammation, characterised clinically by (*a*) extensive brawniness of the lids; (*b*) the presence of a membrane which infiltrates the substance of the lids, subsequently separating by suppuration, leaving a raw granulating surface; and (*c*) running a severe course with constitutional symptoms. The second group contains cases of simple membranous conjunctivitis, characterised by the presence of a pellicular membrane, easily detached from the underlying red but not necessarily raw surface; these cases run a mild course. Other authorities—for example, Nettleship[2]—have argued that all cases of conjunctivitis with false membrane are diphtheritic, and that cases occur showing all intermediate stages between the two varieties above mentioned. At the present time the presence of Löffler's bacillus diphtheriæ is supposed to be the true criterion of the diphtheritic nature of an inflammation. I am not aware of any systematic examination of a series of cases of membranous conjunctivitis with a view to determine the presence of the bacillus. Cases have been recorded which clinically were to be regarded as "diphtheritic" (in the sense used by von Graefe) in which the bacillus was not found; and, on the other hand, the bacillus has been present in cases which would have been regarded as cases of simple membranous conjunctivitis. From a clinical and therapeutic point of view the value of the bacillus in diagnosis is somewhat diminished by the fact that it varies much in virulence, and these variations are unaccompanied by any morphological difference. My experience of this and other cases leads me to the conclusion that the clinical picture of diphtheritic conjunctivitis is quite definite, and that all cases of membranous conjunctivitis can be divided for the purpose of prognosis and treatment into the true "diphtheritic" and the simple membranous, and this is all that is really needed. This case is also of interest from the point of view of treatment. Quinine lotion has been especially advocated by Mr. J. Tweedy[3] on theoretical and clinical grounds; and as in this case no bacilli could be demonstrated after its employment additional evidence in its favour is furnished from the purely pathological standpoint, though doubtless the negative result later is partly to be attributed to the antitoxin injection. Local antiseptic treatment is clearly indicated in these cases, in addition to antitoxin injections, as other pathogenic organisms are almost invariably present. I am indebted for the bacteriological examinations to Mr. H. J. Curtis, assistant to the Professor of Pathology in University College.

BRITISH HOSPITAL, BUENOS AYRES.

THREE CASES OF ABSCESS OF THE LIVER.

(Under the care of Dr. J. O'CONOR.)

THE first of these is a good example of an ordinary case of abscess of the liver, the signs and symptoms were distinctive, and the operation of evacuating the contents of the abscess was rendered extremely simple by the complete adhesions which had occurred between the liver and the abdominal wall over the abscess. The two other cases are in striking contrast to this. In the second case the co-existence of an abscess in the liver with an empyema naturally suggested that the latter was the result of the abscess, especially as all the symptoms were greatly relieved for three weeks after operation. Though a second abscess of the liver was suspected, it was not found even after repeated searches with an aspirating needle, a sufficient proof of the untrustworthiness of this method of looking for small abscesses in this organ. The circuitous route taken by the pus to reach the right pleural cavity is very remarkable. In the third case the difficulties of diagnosis were great, especially in a country where enteric fever is endemic.

CASE 1. *Abscess of the liver; hepatotomy; recovery.*—A man, aged thirty-eight years, was admitted into the British Hospital, Buenos Ayres, on Oct. 15th, 1892. For the previous six weeks he had suffered from nocturnal fever, occasional shivering fits, loss of flesh, sweats, and a constant pain in the right sub-costal region, with an occasional stabbing pain near the inferior angle of the scapula. On examination a slight fulness was visible below the right costal margin; on palpation there was marked tenderness, with fluctuation and downward movement on inspiration, and on percussion there was absolute dulness. The temperature in the evening on the day of admission was 102·6° F. The tongue was furred; there was much thirst, and he had profuse perspiration. On the following morning chloroform was administered and a two-inch incision made over the swelling. On incising the peritoneum, as the liver was found to be adherent, a director was pushed into the liver substance; at a depth of a quarter of an inch an abscess was struck and pus escaped along the groove in the instrument; the opening was further enlarged by Hilton's method, and two pints of grumous pus were evacuated, a large drainage-tube was then inserted, and the cavity was irrigated with warm Condy's fluid. By the third evening constitutional symptoms had disappeared, and he was discharged recovered on the forty-first day. He has frequently reported himself during the past four years, and remains in normal health. He suffered from enteric fever and dysentery in 1891. There was no history of malaria.

CASE 2. *Abscess of the liver; empyema; trans-thoracic hepatotomy; death; necropsy.*—A man, aged twenty-one years, was admitted into hospital on Aug. 10th, 1893, complaining of cough, dyspnœa, and severe pain on the right side of the thorax. The patient's past history was excellent, with the exception that he had suffered from an attack of enteric fever in 1892. Three weeks before admission he had to stop work owing to pain, rigors, sweats, and fever. A week later he developed a most incessant cough, with much offensive sputum. On examination after admission the patient was seen to have a very anxious look; he was bathed in perspiration; the tongue was furred and dry; the temperature was 103·4° F.; the pulse was 120; and the respirations were 40. He had a constant cough, with most fœtid expectoration. He lay on his right side, and the least movement caused alarming dyspnœa. The right side of the thorax did not expand on inspiration, and intercostal fulness was visible from the third rib downwards. There was absolute dulness extending anteriorly from the third costal cartilage to the umbilicus, and in the axillary line almost to the level of the iliac crest. On auscultation there was absence of breath sounds below the third space. Bronchophony and pectoriloquy were well marked. The patient complained very much of tenderness on percussion, and there was absence of tactile fremitus. The liver was felt enlarged down to the level of the iliac crest, but no fluctuation could be detected below the ribs. The temperature on the evening of admission was 105·4°, and during the following twenty-four hours he had several rigors. On the 12th an aspirating needle was inserted into the right pleural cavity, and a few drachms of chocolate-coloured pus were drawn off. Chloroform was immediately given; three and a half inches of the sixth rib were excised in the axillary line, and about four pints of most fœtid pus were evacuated from the pleural cavity. The diaphragm was found to be pushed upwards by a tense fluctuating swelling; a careful search was made for an opening in it, but none was found. The diaphragmatic pleura and diaphragm were next incised, and as the liver was found to be adherent, a large curved trocar was inserted, and six pints of grumous pus were removed. A large drainage tube was placed in the abscess cavity, and no sutures were introduced into the external wound. On the first evening after the operation the temperature was 101·2°, the breathing was greatly relieved, and the cough was considerably diminished.

Digitized by Google

After this the abscess cavity was irrigated twice daily, and by the tenth day all symptoms of septic poisoning had vanished, the temperature remained normal, no pus came from the cavity in the liver, and there was only a slight serous discharge from the pleura; cough and expectoration had ceased. There was nothing to record for the following twenty days; the patient ate well, rapidly gained weight and strength, and was allowed to be out of bed. On Sept. 10th the temperature suddenly rose to 102·5°. A large leaden probe was immediately passed into the liver sinus, which was found to be patent, contained no pus, and had contracted considerably. The probe was then moved freely about in the pleural cavity, some adhesions were broken down, but nothing was found to account for the temperature. During the night the patient had a rigor, and on the following morning as the temperature was 100° the same searching process was repeated. An aspirating needle was inserted into the liver at five different spots, but no pus was struck. On the 12th about a teaspoonful of pus was noticed in the dressings. The pleural cavity was again examined and the aspirating needle again made use of, but all in vain. Constitutional symptoms gradually returned. A few drachms of pus were noticed at each dressing. Search for the cause was frequently made, but in vain, and the patient died on Oct. 20th.

Necropsy.—At the post-mortem examination a healthy granulating sinus was found passing obliquely downwards from the upper border to the centre of the liver substance; this was all that remained of the large cavity out of which six pints of pus had been evacuated. Three inches internal to this sinus a small abscess was found containing two ounces of pus, this was quite superficially located in the upper border of liver, beneath the sixth chondro-sternal articulation, from this a small sinus passed through the diaphragm and opened into the anterior mediastinum, where a localised collection of some three ounces of pus was found, and this in turn communicated by a small opening of about the diameter of a cedar pencil, with the right pleural cavity, and around this aperture a few drops of pus were seen. There was no trace of any communication between the small abscess cavity and the healthy granulating sinus.

CASE 3. *Abscess of the liver; trans-thoracic hepatotomy; recovery.*—A sailor, aged thirty-seven years, was admitted to hospital on June 2nd, 1893, complaining of pain in the abdomen, diarrhœa and fever. Ten days before admission he stated that he was suddenly seized with cramps and diarrhœa unaccompanied by rigors or sweats. There was a history of dysentery ten years before; he had never had malaria or enteric fever. On admission the temperature was 100·6°F., the tongue was furred in the centre; he complained of headache, and pains in the back and legs, there were marked gurgling and tenderness all over the abdomen, no rose spots and no enlargement of liver or spleen were observed; the other organs were normal. With these symptoms and the history of onset, enteric fever was diagnosed, he was placed on the usual milk diet, and a quinine mixture was ordered. During the following four weeks, nothing occurred to alter the diagnosis. The temperature ranged from 100° in the morning to 103° at night; there were no sweats or rigors; the diarrhœa, which he had for some days after admission, ceased and was succeeded by constipation. The liver and spleen were percussed and palpated twice weekly, but no enlargement or particular tenderness was noticed. On July 1st the night nurse reported that the patient had perspired profusely during the night, and as the nocturnal temperature did not show any tendency to diminish, tuberculous ulceration of the intestines was suspected. The night sweats continued during the month of July, the lungs were frequently examined, but nothing abnormal was found. On the 28th for the first time, he complained of a dull pain in the right scapular region, and as the pain was increased on deep inspiration, pleurisy (tuberculous) was suspected, but on examination no evidence of it could be elicited, and no appreciable enlargement of the liver could be detected. On Aug. 14th the patient was extremely despondent, very emaciated, and was sweating continuously; a short hacking cough had been noticed for a few days; and on examination on this date marked tenderness was for the first time noticed in the right ninth intercostal space, a little in front of the axillary line. At last it was decided to explore the liver; a long hypodermic needle was inserted at the tender spot, it soon entered a cavity, and a few drops of grumous pus were withdrawn. The needle was left *in situ*, and a straight sharp-pointed bistoury was entered beside the needle, into the abscess cavity, the needle was withdrawn, and a closed sinus forceps was pushed in along the blade of the knife; when the end of the forceps was felt free in the cavity the knife was withdrawn, the blades of the forceps were forcibly separated, and eight ounces of pus were evacuated. A medium-sized drainage-tube was then passed into the abscess cavity, and the latter irrigated with warm Condy's solution until the fluid returned clear. A rapid convalescence ensued, and he was discharged cured on Sept. 26th. A month later he reported himself fit to resume his work as boatswain.

Remarks by Dr. O'CONOR.—The manner in which the abscess was opened in Case 3 may appear to be somewhat rash, but the patient was in such a low state that it was questionable if he would survive an anæsthetic.

GOVERNMENT CIVIL HOSPITAL, HONG KONG.

A CASE OF DELIRIUM TREMENS; SUDDEN HYPERPYREXIA; NECROPSY.

(Under the care of Mr. J. BELL.)

HYPERPYREXIA is decidedly of rare occurrence in delirium tremens, and when it does appear the prognosis is exceedingly unfavourable, but recovery may result in some of these cases. Dr. A. V. M. Anderson[1] has reported a case of alcoholic delirium in which an axillary temperature of 108·4° F. was noted, yet by the persevering use of ice-packs the temperature was brought down to normal and recovery ensued.

A Danish captain, aged forty-seven years, was admitted to the hospital at noon on Aug. 10th suffering from the effects of "a jolly good bust," as he described it. His temperature was normal and he was very cheerful, being still slightly under the influence of liquor. Vomiting being his chief complaint he was given effervescing mixture with fifteen minims of tincture of opium every three hours. A mustard plaster was applied to the epigastrium and he was ordered a low diet. In the evening he was better, the vomiting had ceased, and he had been able to take some milk and chicken broth. His tongue and breath were still very foul. He was given four grains of calomel and a draught containing half a drachm of bromide of potassium, and twenty minims of liquor morphinæ were given later as he could not sleep. On the 11th he was better, but he had not slept nor had his bowels acted. He was ordered ten grains of compound colocynth pill at once, to be followed by two ounces of Hunyadi water. The effervescing mixture was continued. His temperature was normal, and he was taking his food well. In the evening he had forty minims of liquor morphinæ. He was now quite sensible and quiet, and expressed himself as feeling much better. On Aug. 12th Mr. Bell was sent for at 9 A.M. and found him dressed and in a great hurry to be off to see his Consul. His temperature was normal, and the bowels had acted freely, but he had not slept. He thought the crew were outside trying to get at him, and he had the usual restless movements and talking of a patient suffering from delirium tremens, though he was quite easily managed and reasoned with. After a consultation with Dr. Atkinson he was at 10 A.M. removed to the lunatic asylum, walking there himself—a distance of 300 yards. At 12.30 P.M. he had "a fit," became unconscious, and his temperature was found to be 105°. He was at once placed in an ice-sheet, with an ice-bag to his head, and bromide of potassium and antipyrin were ordered every three hours. The temperature, however, rose rapidly to 109·8° at 2 P.M., when he died. The usual injections of ether and strychnia were given as soon as signs of heart failure began.

Necropsy.—The brain and meninges were much congested, but no hæmorrhage could be found. The heart was fatty and the liver was enlarged with commencing cirrhosis. No other lesions could be found.

Remarks by Mr. BELL.—I have ventured to report the case, as this complication is, fortunately, a rare one in cases of delirium tremens, and it is remarkable for the sudden and rapid onset of the hyperpyrexia, which was quite uncontrollable by the usual methods.

Reviews and Notices of Books.

Twentieth Century Practice. An International Encyclopædia of Modern Medical Science by leading authorities of Europe and America. Edited by THOMAS L. STEDMAN, M.D. Volume IX. London: Sampson Low, Marston, and Co. 1897.

THIS volume continues the subject of Diseases of the Digestive Organs. The first article is by Dr. Johann Mikulicz and Dr. Werner Kümmel, of Breslau, on Local Diseases of the Mouth; these include diseases of the tongue, of the floor of the mouth, of the gums, of the lips and cheeks, and also tumours affecting the mouth. The sections describing the various forms of tumours met with in this region are particularly interesting and are illustrated by several well-executed drawings.

The reader will find one of the most interesting papers to be the one on Diseases of the Intestines (excluding infectious diseases, parasites, and hernia), by Dr. C. A. Ewald, of Berlin. The article is remarkable for the amount of originality displayed throughout. In speaking of general dietetic measures he sounds a warning note against so-called "diet cards," which have become more and more the fashion during late years, which are supposed to aid the physician and save him the trouble of writing directions for patients, but they are practically made useless by the individual peculiarities of the patient. Dr. Ewald, in the section on Appendicitis, adopts the old classification, Typhlitis and Perityphlitis, and states that he cannot agree with Mr. Treves that "this classification has long since been shown to be unsound," and the reasons for coming to this conclusion are fully given. "The surgeon rarely sees a case of typhlitis, because the large majority rapidly go on to recovery; the cases seen by him are those of perityphlitis or of appendicitis, the symptoms of which are the same as those of typhlitis, and which can be differentiated from uncomplicated inflammation of the cæcum only by the fact that it is not readily recovered from, and for that reason comes under the notice of the surgeon." Equally interesting are the remarks on Intestinal Obstruction.

In a treatise on medicine it is extremely difficult to deal satisfactorily with those subjects which lie in the borderland between medicine and surgery. The surgical treatment of any condition should not be excluded entirely, or the presentation of the subject will be utterly one-sided and incomplete, and, on the other hand, to describe fully the surgical procedures which may be necessary would unduly increase the size of the work. In this volume this difficulty has been solved, on the whole, satisfactorily by Dr. V. P. Gibney and Dr. J. B. Walker, of New York, the authors of the article on Hernia. The descriptions are good, clear, and complete, and the treatment deals to quite a sufficient extent with the surgical portion of the subject. There are, however, a few points in the article which we consider of enough importance to notice in detail. In the account of "partial enterocele" "Littré's hernia" is given as a synonym, but the form of hernia described by Littré was, as has been pointed out by Sir William MacCormac, a hernia containing a Meckel's diverticulum, and to this form should the name of Littré's hernia be limited. The true partial enterocele has been named a "Richter's hernia" from the name of the surgeon who first described it fully; the two forms are entirely different in their origin and should be carefully kept distinct. The definition of a strangulated hernia given by the authors on page 334 is as follows: "A hernia is strangulated ..... when its neck has become so compressed that it can no longer be reduced into the abdominal cavity, and when at the same time there occurs an arrest of the circulation in the bowel and in its wall." The irreducibility of the hernia is in itself of comparatively little importance and should not be put forward as the chief characteristic of a strangulated hernia, for it may occur without any strangulation; the essential feature of a strangulated hernia is the interference with the circulation in the vessels of the wall of the bowel; even the interference with the flow of the intestinal contents is of less vital and immediate importance. The authors correctly say that the veins are first obstructed and later the arteries, but this persistence for a time of the blood flow in the arteries is not due to "the arterial walls being more elastic," but to the blood pressure in the arteries being so much greater than the pressure in the veins. The extent to which "taxis" should be employed in the treatment of strangulated hernia has always been a difficulty to the inexperienced. An extensive use of the method was justifiable when herniotomy was frequently followed by a fatal result, but nowadays taxis should be used only in recent cases, and only once; should taxis fail immediate recourse should be had to operation. This is now so generally recognised that we are surprised to find the authors advising that taxis "should be continued for not more than five to ten minutes at a time, and then repeated after an interval of thirty to forty minutes up to five or six hours after the onset of strangulation." Such treatment may be successful in relieving a case here and there, but the risk is very great, especially when the facility and safety of herniotomy are considered.

Dr. Alfred Hengel writes on Diseases of the Spleen, but although the various morbid conditions are fairly well described the paper is scarcely equal in general merit to those already noticed.

The next article is on "Diseases of the Liver," by Dr. Mariano Semmola and Dr. Carlo Gioffredi, of Naples. These authors have succeeded in producing one of the best essays on these diseases that we have met with in any publication. We have not sufficient space to review the article with the fulness which it merits, but we would especially draw attention to the section on the General Pathology of the Liver. Peculiarities of the Hepatic Circulation and their Importance in the Pathology of the Liver are first noticed, and then follows a most complete consideration of the relations of the liver and the intestine, pointing out that in the diagnosis of functional gastro-enteric disturbances of obstinate and rebellious character the physician ought never to forget to look for diagnostic points which may reveal the insidious and as yet concealed disturbances of hepatic function as the true cause of the digestive disturbances. Equally interesting are the remarks on the Relation of the Liver to Auto-intoxication. The authors point out that the protective action of the liver is shown most markedly in intestinal intoxication, and that a diminished functional activity of the liver gives rise to auto-intoxication, whilst, on the other hand, should this condition arise from other causes, functional or pathological changes are produced in the liver. The relation of the liver to infections is also discussed, especially with regard to malaria, typhoid fever, small-pox, cholera, and septicæmia. The relations of the liver and the blood, kidneys, heart, and nervous system are also duly considered. The General Symptomatology of the Liver is most interesting reading and contains a large amount of information. The classification adopted for the varieties of cirrhosis of the liver is a sound one, being based upon its pathology. Dr. John B. Murphy writes on Diseases of the Gall-Bladder, and his contribution will well repay perusal.

The volume ends with an article on Movable Kidney, by Dr. Kendal Franks, of Johannesburg, South Africa. With regard to the frequency of this condition the author summarises thus: (1) mobility of the kidney is more frequent than is generally supposed (from 3 per cent. to

Digitized by Google

10 per cent. of adult women); (2) it is found more frequently in women than in men (about six to one); and (3) it is more common in the right than in the left side (about eleven to one); and ascribes the infrequency with which mobility of the kidney is discovered after death to "the more or less post-mortem fixation which takes place." The symptoms of movable kidney are concisely described and the treatment is judiciously considered. Nephrorraphy is only recommended when the symptoms are very severe and no relief is obtained by any external support.

LIBRARY TABLE.

Die Diagnostik Innerer Krankheiten Mittels Röntgenstrahlen. Zugleich Anleitung zum Gebrauch von Röntgen-Apparaten. Von Dr. Med. GEORG ROSENFELD. (*The Diagnosis of Internal Diseases by Means of the Roentgen Rays, together with an Introduction to the Use of the Roentgen Ray Apparatus.* By Dr. GEORG ROSENFELD.) Wiesbaden: Verlag von J. F. Bergmann. 1897. Pp. 98. Price Marks 2.80.—One of the earliest of the utilitarian applications of Professor Roentgen's discovery was its employment for the tracing of needles, bullets, &c., in the tissues of the living body, as well as for the inspection of fractures and dislocations occurring in the extremities, and soon after the adoption of the new method as a recognised means of surgical diagnosis it was found to be capable of rendering much assistance in the more difficult problems connected with the investigation of the contents of the thorax and abdomen. The present volume, by Dr. Rosenfeld, of Breslau, is an important contribution to our knowledge of this part of the subject, giving within moderate compass a very large amount of practical instruction in the methods of examining patients, interpreting the appearances, and managing the apparatus. The opening chapters are devoted to the head, face, and neck, the chief points of interest being the discovery of bullets in the head, of various foreign bodies in the eye, orbit, air-passages, or œsophagus, and of fluid in the maxillary antrum. Most metallic objects are, of course, easily seen; fish bones, however, are only visible under exceptional circumstances. With regard to the thorax Dr. Rosenfeld asserts that the pictures thrown on the fluorescent screen by the Roentgen rays not only give almost as much information regarding the dimensions and relative position of the viscera as can be obtained from a post-mortem examination, but have the further great advantage that the vital movements are distinctly visible. After a minute description of the contour lines of the heart, together with an account of the diversities of its appearance in different individuals as displayed on the screen, he proceeds to show how by means of photography and the fluorescent screen the observer may arrive at measurements of the living heart which are, he says, far more accurate and satisfactory than any results of auscultation and percussion. The method adopted was the placing of metallic sounds on the chest in positions ascertained by viewing the respective images on the screen, and the various positions being marked on the skin the included area was subsequently measured off. Several precautions are mentioned which must be attended to in order to avoid errors. In a considerable proportion of cases it is possible to define even the inferior outline of the heart, and emphysema, which sometimes makes percussion uncertain, does not in the least interfere with inspection by the Roentgen rays. Hypertrophy of the left ventricle and dilatation of the right side of the heart can be immediately recognised; the great vessels are usually difficult to see on account of the shadow cast by the sternum, but aneurysms and dilatations of the aorta come into view as soon as they extend beyond the margin of the bone. Something may be learned regarding the physiology of respiration by observing the motions of the diaphragm. It will be seen, for instance, that during inspiration the heart does not descend with the central tendon of the diaphragm and the phenomena of hiccough present a curious spectacle. The healthy lungs are almost transparent to the rays, but infiltrations are readily perceived, especially those due to pneumonia, gangrene, and tumours; in phthisis the appearances are much less distinct than might have been expected, and considerable practice is necessary for drawing correct inferences in these cases. Passing over some thirty pages which relate principally to the examination of the abdominal viscera we come to a short chapter on the Injurious Effects of the Rays. Dr. Rosenfeld considers that the dermatitis which is sometimes observed is due, not to the rays themselves, but to the brush discharge of high-tension currents. The continuous inhalation of ozone by the experimenters is, however, a more serious matter. When this gas forms a minute proportion of the atmosphere it is believed to be wholesome; but von Binz and von Schulz have proved that when inhaled in quantity it is a poison, producing hæmorrhages into the mucous membranes and pathological changes in the blood-vessels, and it is noticeable that two workers in this field—Professor Oppenheim and Professor Bucka—although habitually in excellent health, both died suddenly. The volume is illustrated with four full-page photo-prints, showing respectively a gangrenous patch in the lung, enlarged mediastinal glands, the thorax and abdomen of a girl, and a young child from the knees to the lower part of the face.

The Yew Trees of Great Britain and Ireland. By JOHN LOWE, M.D. Edin., F.L.S. London: Macmillan and Co. New York: The Macmillan Company. 1897.—If England owes any part of her greatness and supremacy of the seas to the brave old oak which supplied her with ships she ought certainly to venerate the yew, which supplied her with the bows and arrows that helped her to win some of her earliest victories. Yet while the oak has always inspired feelings of reverence and awe the yew has ever been associated with all that is sombre and gloomy. The story of the yew, however, forms one of the most fascinating chapters in our English folk-lore, and the embodiment of Dr. Lowe's investigations in book form will be heartily acceptable to all lovers of the romance of trees. Beginning with a chapter on the etymology of the name and the varieties of the yew the author goes on to deal with its distribution and growth. He discusses the vexed question why the tree is to be found planted in so many places in churchyards, and quotes the various statutes relating to the tree. The hard, tough, close-grained, and durable nature of the wood has caused it to be used for many purposes besides the manufacture of bows and arrows. Formerly it was much used in the manufacture of Tunbridge ware, posts to be fixed in the ground, cogs for mills, and "everlasting axle-trees," as Evelyn has it. The wood was also employed in the making of bedsteads, having gained the reputation of keeping away bugs. Drinking tankards were manufactured from it, and, referring to Pliny's assertion with regard to the ill repute of vessels made from this wood, the author believes that it is possible that wine, if allowed to stand for some time in a new vessel, might extract sufficient poison to be injurious. Taxin, the active principle of the yew, however, seems to be insoluble in water, and at the present day yew is the favourite material for making cups in the Pyrenees. The poisonous nature of the tree has been referred to from early times by Dioscorides, Nicander, Galen, and others, and we have it on the authority of Suetonius that the Emperor Claudian caused an edict to be published to the effect that this tree had the power of curing the bite of vipers. Virgil alludes to the flowers as communicating poisonous properties to Corsican honey, but the author remarks that if the tree existed in Corsica in Virgil's time it must have been for some reason or other eradicated, for he has not met with a

Digitized by Google

single tree of this species in any part of the island. The question of the poisonous nature of the yew has never yet, so far as we are aware, been definitely settled, and the statement by Dr. Lowe that "every part of the plant is more or ess poisonous with the exception of the red mucilage surrounding the ripe seeds" is an important one. A writer in Knight's English Encyclopædia says that the fruit of the yew may be eaten with impunity, and the statements with regard to the poisonous nature of the plant are most conflicting. It has been said that small doses of the leaves of the plant have an effect similar to that of digitalis in reducing the circulation. The author's experiment made upon himself with taxin would show "that it is a cardiac tonic of no mean value. The heart's action is decreased in frequency by small doses such as 1-20th to 1-8th of a grain at the same time that the cardiac pressure is distinctly increased. These effects I have found to be durable. In larger doses it generally depresses the heart's action. On the whole, it contrasts favourably with digitalis and convallaria and is worthy of more extended observation." That the yew is poisonous to animals is well known, but experiment has proved that the leaves when mixed with two or three times their quantity of oats can be taken by horses with impunity. The volume is well printed and well illustrated, and contains a bibliography.

The A B C of the X Rays. By WILLIAM H. MEADOWCROFT. London: Simpkin, Marshall, Hamilton, Kent, and Co.—This book is written essentially for the tyro, and contains simple directions which are calculated to ensure success in obtaining simple x ray results. We do not agree with the author—at any rate, we have not found it so in our experience—that tungstate of calcium exhibits as much fluorescence as the platino-cyanides. Necessarily there are no directions given bearing on the application of the x rays to the exploration of the cavities of the body.

JOURNALS AND REVIEWS.

The first volume of *The Phonographic Medical Library*, projected by the Society of Medical Phonographers, consists of a shorthand edition of four lectures on the Diagnosis of the Nature of Organic Brain Disease, by Sir William R. Gowers. The fourth lecture is a reprint from Sir W. R. Gowers' standard work on the Diagnosis of Brain Disease; the first and second comprise the opening lecture in the same work, amplified and brought up to date; whilst the fourth, on Acute Meningitis, is new. The style of shorthand adopted is the "easy reporting," and the lithography is clear and well done. Medical shorthand writers ought to consider themselves fortunate to be able to possess for the small sum of 1*s.* 6*d.* an authoritative work, which not only affords excellent practice in reading shorthand, but will be helpful in their daily work, characterised as it is by the clearness of diction and lucidity of thought of Sir W. R. Gowers. The publishers are Sir Isaac Pitman and Sons.

Appleton's Popular Science Monthly (New York, Appleton and Co.).—The number for August contains several papers of medical interest embracing subjects which we do not consider at all desirable for public reading or for treatment in a popular journal. Thus, Dr. T. D. Crothers raises some interesting points on New Questions in Medical Jurisprudence. It is a sound and temperate view of the attitude that should be taken in regard to criminals who have committed a crime under the influence of drink. Of course, alcohol predisposes to criminality by lowering and paralysing those brain centres which preside over consciousness of right and wrong. "The claim," he says, "that alcohol is used for the purpose of committing crime should be a question open for evidence, and one to be considered doubtful until proved by facts that can have no other meaning." "Crime committed when under the influence of spirits will be found, as a rule, to follow uniform lines and be very much alike in methods of execution." Dr. Pearce Bailey contributes a paper, illustrated with cases (!!), on the Thyroid Gland in Medicine, which gives a plain and intelligible statement of the new organo-therapy. Lastly appears a very interesting paper on Stones in the Head which we dealt with in our issue of Sept. 18th. We must repeat that it is not compatible with professional dignity that papers of so strongly and strictly a medical character should be published in a "popular monthly." It is a matter to be deplored that even in America this is countenanced.

Analytical Records
FROM
THE LANCET LABORATORY.

UNSWEETENED SWISS CONDENSED MILK.

(THE BERNESE ALPS MILK CO. AGENCY, EDWIN FISCHEL AND CO., 11, ROOD-LANE, E.C.)

THE convenience of sterilised milk in a concentrated form is obvious. The preparation before us exhibited an excellent composition and very little deterioration in regard to flavour. Analysis gave the following results: total solids, 37·75 per cent.; fat, 10 per cent.; mineral matter, 1·92 per cent.; and water, 62·25 per cent. On diluting the concentrated milk by adding to every one part by weight two parts of water, milk of the following excellent composition was obtained: total solids, 12·58 per cent.; fat, 3·33 per cent.; and mineral matter, 0·65 per cent. The concentrated milk contained no antiseptics, and was perfectly sweet and sound to the taste. It is a food product of considerable merit

PURE CONFECTIONERY.

(TUCKER AND SONS, 73 AND 75, HIGH-STREET, TOTNES, DEVON.)

Materials are much too cheap nowadays to make it profitable to employ objectionable adulterants in the preparation of sweatmeats. At one time, of course, as THE LANCET Analytical Commission in 1854[1] showed, confectionery was fraudulently as well as injuriously adulterated. The specimens before us, however, are not even made from common materials, but in some cases with cream and honey. The taste certainly indicates the selection of the best materials, while analytical examination proved the absence of objectionable ingredients. It is satisfactory to find that a high standard of purity and perfection is aimed at by the selection of choice ingredients. The samples submitted to us included butterscotch, cream and honey tablets, Devon cream toffee, and honey and mint toffee, the latter containing a definite proportion of, it is said, Mitcham mint. Not the least distinct advantage of toffee and its preparations is the practical impossibility of employing aniline dyes for colouring purposes.

CACAO DE LUXE.

(A. SHORT AND SON, 1, STANLEY-STREET, GLASGOW.)

The following results were obtained on examination of this cocoa: fat, 31·20 per cent.; mineral matter, 6·20 per cent., the alkalinity of which was equal to 2·43 per cent. reckoned as potash. The cocoa is distinctly alkaline in reaction, a feature which distinguishes it from Dutch cocoas. The Dutch method does not consist of the addition of an alkali to the cocoa, but of a small proportion of a neutral salt which, on ignition, is converted into free alkali. The cocoa employed is evidently of a superior kind and the bulk of

[1] The Analytical Sanitary Commission on Poisonous Coloured Confectionery, THE LANCET, March 18th, 1854, p. 316

Digitized by Google

the indigestible fat of the original bean is reduced. With regard to miscibility with water, however, there is margin for improvement.

NESTOR FLUID.

(THE NESTOR SANITARY FLUID CO., 16, CREECHURCH-LANE, E.C.)

Tar acids, mainly cresol and not phenol, and tar oils combined with alkali are the basis of this preparation. With water it yields a milky fluid, and in this finely divided condition the powerful antiseptic oils are most favourably presented. The preparation is strongly alkaline, mixes in all proportions with water, and owing to the particular method of combination it gives a mixture of uniform composition and antiseptic strength. It is practically free from carbolic acid, and on this account is regarded as non-corrosive and non-poisonous. This, however, as experience has shown, is not absolutely correct. It would be better to describe it as much less poisonous than preparations of carbolic acid. "Nestor Fluid" is a powerful antiseptic and disinfectant preparation, more than equalling carbolic acid in this respect, and in many ways preferable for ordinary disinfecting purposes.

KOLLOX WINE.

(THE KOLLOX WINE CO., 69 AND 70, MARK-LANE, E.C.)

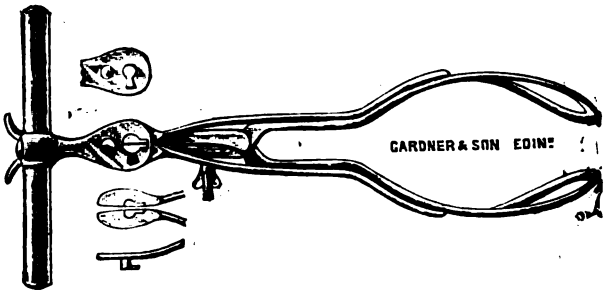
On analysis this wine yielded the following results: alcohol, by weight 17·25 per cent., by volume 21·19 per cent., equal to proof spirit 37·13 per cent.; extractives, 7·27 per cent.; mineral matters, 0·19 per cent. It is stated that the wine is prepared from selected port to which a specially prepared fluid beef has been added, and a definite proportion of the principles of the kola nut. We were able to confirm this statement in part since the alkaloid occurring in the kola nut, caffeine, was successfully isolated and identified, but if fluid beef has been added the proportion contained in the finished wine must be very small and of little value. We found only ·0246 gramme of nitrogen in 100 c.c. of the wine. By adopting the factor 6·25 as multiplicator this at most represents only ·16 per cent. of meat derivatives. This fact detracts not a little from its claim as "a food tonic." The wine is excellent to the taste and evidently prepared from a good and sound port.

THROAT PASTILLES (MENTHOL CO.).

(GLAISYER AND KEMP, 11 AND 12, NORTH-STREET, BRIGHTON).

These pastilles consist of a kind of jujube, each containing menthol, $\frac{1}{5}\frac{1}{5}$ grain; cocaine, $\frac{1}{2}\frac{1}{5}$ grain; and red gum. They dissolve slowly in the mouth and are not disagreeable to the palate, a slight but quite distinct anæsthetic effect being experienced in the throat soon after the pastille is dissolved. We had no difficulty in isolating and recognising the constituents indicated. These pastilles will afford a useful form of application in certain affections of the throat.

GREEK BRANDY.



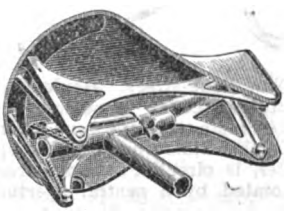
(ACHAIA, DEUTSCHE ACTIENGESELLSCHAFT FÜR WEIN PRODUCTION, PATRAS, GREECE.)

The attention of the profession may be well directed to the fact that since the failure in the Cognac district some years ago excellent grape spirit is being sent to this country from other fields, notably Greece and Spain and the colonies. Though these spirits are not produced in the famous Cognac district, they should claim a decided preference over spirit that is derived from maize and other cereals. The sample of Greek brandy submitted to us possessed the distinctive fragrance of wine brandy, and was smooth and mellow to the taste. With still longer keeping it would doubtless further improve in these particulars. Our analysis furnished the following results: alcohol, by weight 40·80 per cent., by volume 48·21 per cent., equal to proof spirit 84·49 per cent.; extractives, 0·41 per cent.; mineral matter, 0·02 per cent.; acidity, reckoned as acetic acid, 0·08 It is obviously a genuine grape-derived spirit, and it offers, therefore, distinct advantages, especially for medicinal use. Though somewhat dark in colour it does not contain an excessive amount of extractive matters, while its alcoholic strength is satisfactory.

New Inventions.

AXIS-TRACTION FORCEPS.

IN the following illustration is shown a simple device for fixing the traction handle to the rods in the Simpson Axis-traction forceps and at the same time locking the traction rods. The figures (which explain themselves) show, in place of the usual stud on each rod, half a stud on each rod, set upon the adjacent edges in such a way that when approximated they form one stud, which with the hole and slot in the traction plate forms a joint on the well-known Péan principle.



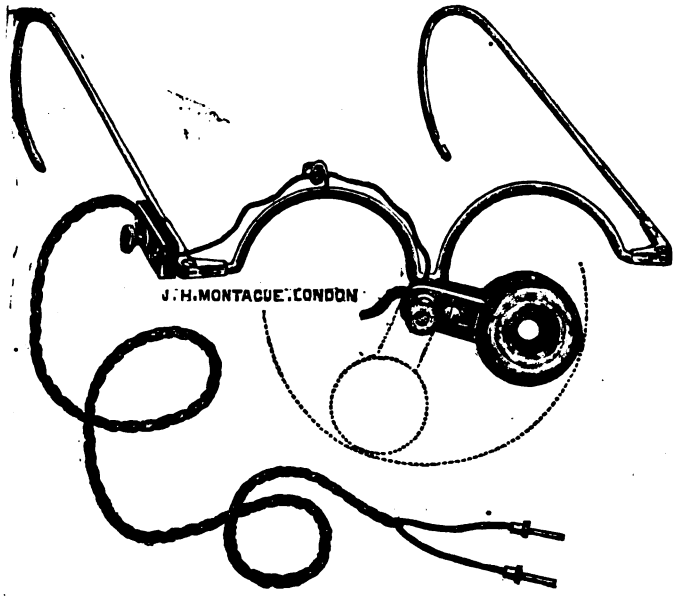
The advantages claimed are:—1. Simplicity of mechanism, giving (*a*) cleanliness and (*b*) a saving of time. 2. Rigidity, the traction apparatus forming a triangle with force applied at the apex instead of a polygon with force down two opposite sides. 3. Uniform ease of adjustment for all sizes of head and all grips, good and bad. The pair from which the illustration is taken was made at my suggestion by Messrs. Gardner and Son, of Edinburgh, and I find that it works very satisfactorily, whilst I can apply and remove the traction handle in half the time required for other methods. It costs no more than others.

Auckland, New Zealand. F. M. PURCHAS.

THE ESMOND SADDLE.

NOTWITHSTANDING the padded and pneumatic saddles which have been placed upon the market many riders still prefer the ordinary leather peaked saddle, and, perhaps, if properly moulded and adjusted, there is little to be said against it. The Esmond saddle so far as the "seating" accommodation goes is similar to the common form of peaked saddle, but is original in the manner in which the seat is attached to its supporting framework. The construction is such that the seat swings longitudinally, and at the same time there is a slight lateral movement. Both these movements are of importance—the first in preventing shock when the wheels meet with any obstacle, and the second in preventing friction between the saddle and the thighs of the rider. Another advantage is that as the rider practically becomes one with the saddle, the latter moving with him, there is no danger of bruising the perineum by jolting on to the peak of the saddle. Vibration is also greatly reduced, and there is a sense of ease and comfort in riding which does not pertain to the ordinary saddle. The address of the Esmond Cycle Saddle Company is Botolph House, Eastcheap, E.C.

"THE ALFORMANT."



THIS is an apparatus specially adapted for the easy production of formaldehyde gas for the disinfection of the air of apartments. It consists simply of a spirit lamp provided

Digitized by Google

with a glass chimney, over which is placed a cup-shaped metal receiver, in which a tablet yielding formaldehyde is dropped. The tablet itself is a condensation product of formaldehyde—that is, paraformaldehyde,—which is a solid at ordinary temperatures. On heating this substance formaldehyde gas is disengaged, which, from a single tablet, is sufficient, it is stated, to render 1000 cubic feet of air sterile. The powerful disinfectant, antiseptic, and deodorising properties of formaldehyde have now been fairly established, and a simpler way of applying disinfection to rooms, articles of clothing, &c., can scarcely be suggested. A very important advantage gained in employing formaldehyde for this purpose is that it is without destructive action upon articles of furniture, brass fittings, or domestic fabrics. The gas is very irritating to the mucous membrane, suggesting at one moment sulphurous acid and at another bromine. The introduction of formaldehyde in the form of paraformaldehyde tablets, which yield on heating two and a half times their weight of gas, renders disinfection, and especially aerial disinfection, a much more satisfactory and convenient operation than was possible hitherto. We should imagine, also, that it would be a very convenient and effectual means of ridding dwelling-rooms of mosquitoes, midges, and other pests. The apparatus, with the paraform tablets, is supplied by the Formalin Hygienic Co., Limited, 9 and 10, St. Mary-at-Hill, E.C.

A NEW SURGICAL LAMP.

THE illustration given below represents a new form of electric lamp made at my suggestion some time ago by

Mr. J. H. Montague, of 101, New Bond-street. Having had frequent opportunities of practically testing its usefulness I have found it very convenient in more than one application, though originally designed for ophthalmic work. The lamp, which is one inch in diameter, is circular, flattened from before backwards, and perforated by a central aperture about a quarter of an inch in diameter; the filament completely encircles this aperture. The back of the lamp is silvered and blackened round the central hole behind, and to avoid any unpleasant radiation of heat to the eye the back is further protected with non-conducting asbestos material A small transformer is required for use with the alternating current, the lamp working best at about twenty-three volts. At present this lamp has been tried in two forms—(1) attached to a handle provided with a switch, and (2) fitted to a laryngoscopic frame (as illustrated) in which it is hinged to the bridge so as to be readily adjustable for either eye; a switch is fixed to the right side of the frame, which can be turned on or off by the slight movement of a small milled head. The advantages of this lamp consist in its lightness as compared with a laryngoscope mirror, of which it takes the place, and more especially in its rendering the usual bracket lamp unnecessary, thus obviating the frequent adjustment of this and of the mirror which is generally required, for the lamp once fixed satisfactorily in the line of vision needs no further alteration whatever the movements of the observer or patient. The uses to which this lamp can be put are many; the most important are for indirect ophthalmoscopic examination (here the laryngoscope frame is very convenient, for it leaves the hands free), for laryngoscopy, and for examination of the ear and nose. It is also applicable to the urethroscope.

Harley-street, W. H. R. BELCHER HICKMAN, M.B.Oxon.

THE "MATTO" CHAIN.

THE essential part of the Matto Chain consists of a stout wire frame, three inches wide by twenty-five inches long, which carries twelve rows of wooden balls, which are free to rotate, each row containing two balls. The diameter of the balls is about one and a quarter inches and the axes are two inches apart. At each end of the frame is provided a suitable handle. The appliance consists, in reality, of a chain of squares, each square carrying at the anterior and posterior ends two revolving balls. Each square has independent movement, so that the chain adapts itself to the shape of the body. Though we cannot regard it as a means of obtaining the complete action of the massage process, yet it distinctly imitates the manual kneading of the muscles of that process, and in this way may establish circulation and induce an invigorating reaction. As each ball rolls over the muscular tissue it is alternately depressed and relaxed, to be depressed and relaxed again as succeeding balls pass over its surface. The effect, however, obviously depends upon the amount of pressure applied when the chain is in motion over the parts it is required to stimulate. To apply any considerable pressure so as to gain distinct effect requires a decided expenditure of energy, and there are many patients who would be benefited by massage, yet who would not have the strength and endurance to satisfactorily manipulate the chain for themselves. It affords, however, for this very reason a very healthful muscular exercise to those who are not too weak to apply it, and its value in this respect is enhanced since at the same time it induces circulation and stimulates the muscles over which the balls travel. Another point to be noticed is that on applying the chain to the body the balls at first impart a feeling of cold, but this discomfort could obviously be avoided by slightly warming the apparatus just previously to use. The Matto Chain is supplied by "Matto, Limited," 32 and 34, Clerkenwell-road, London, E.C.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next examination for the certificate in nursing and attending on the insane will be held on Nov. 1st, 1897, as already announced in our advertisement columns. Candidates should obtain from the Registrar (Dr. Spence, Burntwood Asylum, near Lichfield) a schedule, to be filled up, signed, and returned to him at least four weeks before the date of the examination. Oct. 4th will be the last day upon which, according to the rules, candidates can enter for the November examination.

INFECTIOUS DISEASES AT CARDIFF.—During the thirteen weeks ended July 3rd, 101 patients were admitted into the infectious diseases hospitals at Cardiff, compared with 151 in the preceding three months. Of these 71 were suffering from scarlet fever, 22 from diphtheria, and 8 from typhoid fever. The expenditure for these amounted to £641 3*s.* 6*d.*, or, after deducting £17 7*s.* 7*d.* received from the guardians and others for the maintenance of patients, an average cost of £6 3*s.* 5*d.* for each patient admitted.

THE LANCET.

LONDON: SATURDAY, OCTOBER 2, 1897.

THERE seems to be fair hope of redeeming the cause of Direct Representation in some degree from the discredit which has fallen on it in consequence of the extraordinary action of Dr. RENTOUL. As we anticipated last week, the list of candidates—which we may now regard as complete—contains one or two names which will justify the concentration of the votes of the profession for the purpose of securing the best candidate. We must again repeat that in our opinion the discredit to Direct Representation is at present very great. Dr. RENTOUL has disturbed the profession with proposals or almost promises of a medical millennium—the number of Direct Representatives was to be largely increased; midwives were to be abolished, and the cases they attended were to be handed over by force of law to general practitioners, who were to receive from public sources two guineas per case; friendly societies were to be limited in their powers from a medical point of view; and all gratuitous work on the part of members of the General Medical Council and its committees was to cease. And just as the time draws nigh for Dr. RENTOUL to do his work and demonstrate the practicability of his proposals he retires from his post, throwing the blame on the profession for not supporting him and on the members of the General Medical Council, among whom he stood "almost alone" in desiring "to carry into effect those medico-political and medico-ethical questions which I have had at heart for a good number of years." We do not think that in the history of medical politics there is such another instance of want of courage in the person of a reformer who felt he was almost the only advocate of truth and right. We need not labour these points. They are admitted even by those who supported Dr. RENTOUL. We only refer to them to impress on the profession that no mistake should be made in the rapidly approaching election. A candidate must be chosen who knows his own mind, who can take a sober view of the duties of the General Medical Council, and who can give the members of the Council credit for what they do and for a little common sense and some disposition to act for the advancement of the best interests of the profession—which are certainly consistent with the best interests of the public.

There are now five candidates before the electors, Mr. JACKSON having with some magnanimity retired in favour of Sir WALTER FOSTER. We shall neither surprise nor offend other candidates if we assume that for the purposes of this election the choice of the profession will lie between Mr. VICTOR HORSLEY and Sir WALTER FOSTER. On less serious occasions questions may properly be raised in favour of a general practitioner as such, but this is not the time. A strong well-known candidate must be elected, and so long as he is in sympathy with the body of the profession and its wants, and is a man of stability and ability and discrimination, we need not too narrowly inquire what branch of practice he follows. We may consider the claims of Mr. HORSLEY and Sir W. FOSTER in the order in which they entered into the contest. They are both men of ability and eminence, and the election of either of them would tend to restore the somewhat damaged reputation of Direct Representation. The time is not one for bandying compliments, and we shall try in a few sentences to indicate, not only the merits of these gentlemen, but, with all due deference to themselves, their defects.

Mr. VICTOR HORSLEY is one of the most brilliant men in the profession, with the great advantage of youth. He has so distinguished himself in science as to have been elected in early life a Fellow of the Royal Society, and in surgery as to be one of its most original and enlightened leaders. Nevertheless, he has always manifested the utmost sympathy with the general practitioner and he has displayed for years the most keen interest in defending medical men from all unfair conditions and unjust laws. He has, as President of the Medical Defence Union, acquired an almost unrivalled knowledge of the weak spots in the Medical Acts and the deepest sense of what is required for the honour of medical practice. He speaks with great clearness and force. He is, in short, a very strong candidate. Has he no faults? He has the very faults of his virtues. He is impulsive. Sometimes he is prejudiced and occasionally rather too aggressive. He is apt to be borne along with the very impetuosity of his perceptions and convictions. On one or two occasions he has allowed himself to make unwarranted charges against the President of the General Medical Council, which offended not only the President but the Council. But these are faults that responsibility will correct. He remains an excellent candidate, whose election would add immensely to the interest of the Council's discussions and to its reputation.

Sir WALTER FOSTER is, we are all aware, an able consultant and a prominent Member of Parliament. He is a good speaker who knows what he wants to say and how to make his points. He is good-tempered in debate and was always listened to with respect by the Council. His Parliamentary position has some advantage when it does not interfere with his attendance at the Council. He has always shown an interest in needed amendments of the Medical Acts, and was the chairman of a select committee to consider defects in the Registration Acts. The profession, too, has had in him, both in Parliament and as a member of the General Medical Council, an effective and sympathetic exponent of its grievances and complaints. His faults are due to a certain variability of mind. In November, 1889, he proposed a resolution in the Council urging on the Government the importance of passing into law some measure for the education and registration of midwives. In later years he has been the exponent of Dr. RENTOUL'S views and is now strongly supported by him. With a little more firmness of mind he would doubtless have retained his well-earned seat at the last election, but with a doubt either in his own intentions or as to the confidence of the profession he retired. However, when all is said there remain two excellent candidates. It is somewhat hard on the profession that it should have to choose between them.

Digitized by Google

Either of them would confer a great obligation on the profession by giving place to the other and so enabling it to return a suitable candidate with practical unanimity. Mr. HORSLEY, however, was first in the field, and in view of the facts that at the last election he stood aside in favour of candidates who were actually general practitioners, and that on the present occasion he was quite ignorant that Sir WALTER FOSTER would again offer himself for election, his candidature will claim much sympathy. Moreover, his address and his speech at Manchester show how lucidly he comprehends the work to be done in the Council. If elected he would of course have to cease to be a member of the Medical Defence Union; but it is not too much to say that he would take with him an amount of knowledge of the conditions of medical practice and of the defects in medical legislation and in medical education which would add greatly to the usefulness of the General Medical Council.

THE history of therapeutics is full of remedies which have been tried and vaunted for various diseases, but which further experience has shown to be perfectly useless. Every year are added to this list substances of unknown composition and uncertain action. Within recent years, however, certain bodies have been administered which have given rise to a practically new branch of therapeutics—namely, the animal extracts—and this in turn has caused renewed attention to be applied to the properties of "internal secretions." One of the most remarkable of recent remedies which has already withstood the test of time and has not, like so many others, fallen into disuse, is thyroid extract. Experiments have not yet clearly demonstrated the functions of the thyroid gland; but one point is clear, as Dr. ROSE BRADFORD shows in his article on the "General Pathology of Secretion" in Dr. CLIFFORD ALLBUTT'S System of Medicine—namely, that whatever other functions the thyroid gland may possess it supplies at any rate a substance necessary for normal tissue metabolism. At first introduced for the treatment of myxœdema by Dr. GEORGE R. MURRAY and others, feeding with thyroid gland or its extract has been employed in numerous conditions with varying success, but by far the most satisfactory results have been obtained in myxœdema and cretinism.

Four original articles in our present issue bear testimony to this. Especially interesting is one bearing the title "Sporadic Cretinism," by Dr. A. GORDON PATHESON. He describes the case of a child affected with cretinism who was brought to him at the age of eleven months. The effects of the thyroid treatment were immediate and remarkable, and steady improvement had been maintained for a period of five years. The mother gave birth to a second child which was an exaggerated counterpart of the first, and which only lived for twenty minutes; and then follows the most interesting part of the paper. The fact of the mother having given birth to two cretins in successive pregnancies offered a strong presumption that she would, unless treated, give birth to a third, consequently when the woman again became pregnant she was treated from the beginning of the third month by thyroid extract in the form of tabloids. Labour came on naturally and at full term and was easy. The child was a fine healthy female, indistinguishable from any other infant in appearance. Another article by Dr. T. TELFORD-SMITH draws attention to the fact that one of the most marked among the many other signs of development produced in cretins during the administration of thyroid preparations is the rapid increase in stature, and he finds that this rapid growth of the skeleton leads to a softened condition of the bones, resulting in a yielding and tendency to bend in the case of those which have to bear the weight. Surgeon-Captain DRAKE-BROCKMAN records a case of advanced cretinism treated by thyroid extract which showed marked improvement under the influence of the extract. The boy was a native of India, and the case was an advanced one, not only in years, but in severity of symptoms. The fourth case comes from another part of the world—New Zealand—and is reported by Mr. CHARLES MORTON ANDERSON. The patient in this instance was a girl, aged eleven years, who had first shown symptoms of cretinism at the age of three years, so that the condition was far advanced; nevertheless, immense improvement was produced by the use of thyroid extract, both physically and mentally.

Regarding these cases as types of the numerous ones constantly being recorded, it is difficult to find a more marked example of uniformly successful medication. Perhaps the two forms of treatment with most nearly similar histories which present themselves in modern times are those by the salicylates in acute rheumatism and by iodide of potassium in syphilis. Although, as stated above, the exact action of thyroid feeding is not as yet fully understood, yet it has proved by the test of number of cases and by the lapse of time since it was first introduced to be one of our most reliable remedies, and this in a class of case which up to a few years ago had been looked upon as almost hopeless. The condition of the cretins especially was most deplorable, not only as regards their physical but also their mental powers. Now, however, the prognosis of such cases under this treatment is most hopeful, and the use of the thyroid gland or its extract may be regarded as one of the most successful therapeutic discoveries of the century.

THE total number of persons of unsound mind in England and Wales under the supervision of the Lunacy Commissioners on Jan. 1st, 1897, was 99,365. This represents an increase of 2919 for the year 1896. There has been an increase of 2857 pauper patients, 53 private patients, and 9 criminal lunatics. The returns for Scotland and Ireland also show that the asylum population is increasing. At first sight it would appear that insanity in its more active phases is making rapid strides among the populace, but the official view does not confirm this, and the authorities of the various countries are strong in the conviction that the increase is more apparent than real, and is mainly due to accumulation. This assertion is decidedly reassuring, but perhaps it is capable of further proof. An argument in favour of the Commissioners' views is furnished this year by the fact that the death-rate of the English asylums shows a considerable diminution. The effect of a recorded decrease of 0·96 in the death percentage of 1896, as compared with that of 1895, was to leave alive at the end of 1896 722 patients who would have been removed by death if the

Digitized by Google

rate of mortality had been the same as that of the previous year. On the other hand, a slight advance of 0·35 in the recovery rate brought about the discharge of 66 more patients than would have been left if the rate of 1895 had prevailed, and this number must be deducted from the 722, leaving 656 cases as the result of the diminished discharge rate. This is an explanation as far as it goes, but it leaves a very large margin to be accounted for. What is the composition of this residue? Is it due to recent, recurrent, or chronic insanity? This is the point to determine, and in this respect the statistical information afforded by the Commissioners is very defective. No statistics are available for estimating the number of persons *with first attacks* in which the onset of insanity took place *within three months of admission*. A table conveying this information is inserted in every asylum report, and it is therefore safe to assume that the sum total for the whole country could easily be ascertained. For purposes of comparison such a table would prove invaluable, and it is the only method of obtaining anything like reliable information regarding the incidence of freshly occurring insanity; further, it would tend in great measure to solve the difficult question whether there is, or is not, an increased liability to insanity amongst the population. In the Red Book of the Asylums Committee of the London County Council the proportion of such cases appears to be 37 per cent. of the admissions. It would be interesting to know the ratio for the whole country.

While the number of pauper lunatics shows a marked increase from year to year, the case is otherwise with private patients. In the latter class there has been a continuous decrease, from 2·82 per 10,000 of the whole population in 1891, to 2·68 in the present year. During the same period the ratio of pauper lunatics has increased from 26·78 to 29·07 per 10,000 of population. As to the general proportion of insanity, it appears that in 1859 the proportion of officially known lunatics to the population was 1 to 536. Since then things have materially altered for the worse, for the ratio at the present time is 1 to 313. The statistical tables in this year's report have been supplemented by the inclusion of a table giving the number of patients admitted in each month of the year 1895 suffering from the principal forms of mental disorder, and also showing the daily average of those admissions for each month. It is somewhat singular that the admissions under all heads were most numerous in the month of May, next in April, and thirdly in June. The daily averages of admissions for each of the five months March to July exceeded the daily average for the whole year; again, the daily average of admissions of cases of mania was highest in April—viz., 32·3 per cent.; and that of cases of melancholia highest in June—19·3 per cent. The lowest daily average in both cases was in February—viz., cases of mania, 24·3 per cent., and of melancholia, 13·3 per cent. This is a valuable and instructive table which, it is to be hoped, will be continued in future reports; in the form of a chart it would prove still more useful. The conclusion drawn is that insanity requiring early and active treatment away from home, develops more frequently in the spring and summer months than in autumn or winter.

The actual number of recoveries during the year was 7178, an increase of 105 on the previous year. The proportion of recoveries to the total number of admissions comes to 38·53 per cent., as compared with 38·18 per cent. in 1895 The total number of deaths was 6806, being 9·05 per cent. of the daily average number resident. In respect to the assigned causes of insanity, the Commissioners are of opinion that very great reliance cannot be placed on the returns, but apparently hereditary influence continues to be the most fruitful cause, previous attacks coming next, and intemperance in drink taking the third place. The proportion of old age as a cause continues to advance in the pauper class. The cases of relapse also show a tendency to increase in the same class. It is stated that this may be accounted for by the anxiety to discharge patients "not perfectly cured" owing to the crowded state of so many asylums. The Commissioners, having recognised the fact that there is a tendency to premature discharge, ought to consider the feasibility of endeavouring to check it as far as possible, for there can be no doubt that, in addition to frequency of relapse, it is responsible for other evils — viz., an increased production of hereditary insanity, and a larger proportion of insane criminals.

With the opening of the new asylum in the Isle of Wight the total number of county and borough asylums now amounts to 70. The admissions into these institutions during the year 1896 numbered 18,448, and it is noteworthy that the number of new cases admitted was no less than 2513 in excess of the average of the ten preceding years. The percentage of post-mortem examinations made was 79·9, the same as last year. The suicides amounted to 22, but in 6 of the cases the act which resulted in death was committed prior to admission, and in 2 instances the suicide occurred whilst the patients were absent on trial or on leave. 5 deaths were due to misadventure or accident; 2 patients were suffocated during epileptic fits. Many of the county and borough asylums are overcrowded, and in some instances the overcrowding is aggravated by insanitary conditions. The Commissioners express their regret that they are unable to report any material decrease in the number of those asylums where the sanitary conditions are defective, and in which preventable disease occurred. 16 deaths appear to have been due to typhoid fever in 9 asylums, 93 to colitis and enteritis in 31 asylums, 49 to diarrhœa of specific character in 20 asylums, and 6 to erysipelas in 5 asylums.

Attention is drawn to the state of the law respecting idiots, which requires amendment. More adequate provision is needed for the proper care and treatment of lunatics in workhouses. The number of registered hospitals remains the same, and their general condition continues to be quite satisfactory. The same holds good with respect to licensed houses, with a few exceptions. The entries made by the Commissioners on their visits to the county and borough asylums are appended. It is evident that those concerned in the management of these institutions display much vigilance in the care and treatment of the insane. The whole report affords continued assurance that there is no falling off in the efficiency and energy with which the duties of the Lunacy Board are discharged.

"Ne quid nimis."

THE SCIENTIFIC CONSTABLE: A NEW DEPARTURE.

WE have already with us the prescribing chemist, the herbalist, the bone-setter, the "electro-cure" humbug, and a host of advertising quacks, but now it seems that we are to go a step further and to be introduced to the policeman who, having attended a course of ambulance lectures, gives evidence instead of the surgeon, thereby saving the latter's fee and at the same time glorifying himself. In reading the account of an inquest held at Halton, near Lancaster, we notice that after a police constable had given evidence as to the finding of the body a serjeant was put into the box, not to corroborate his colleague, but to describe the injuries and to give an opinion as to the manner in which one of them had been caused. He said: "When we got it out I found that the neck was dislocated, and a large wound on the left side of the neck, through the mouth, and out at the right cheek. The carotid artery was severed, the left arm was fractured and four of the left ribs, whilst the bottom lip was torn away ..... The carotid artery appeared to have been pierced by a piece of timber, the wound being contused." What are we to think of this? In the first place, how is this man competent to say that the neck was dislocated (a very rare accident, we may remark)? Again, not being an anatomist, how can he decide that the carotid artery was wounded, and, above all, how in the name of all that is wonderful can he swear that four ribs were broken? It is a notorious fact that fracture of a rib may be most difficult of diagnosis; but here, where experts often hesitate, we have a policeman glibly dogmatising. But even worse follows. Not being content with speaking to facts, he proceeds out of the fulness of his experience to give the opinion that the wound of the artery was caused by a piece of timber because the wound was contused. It really would be laughable if it were not such a serious matter. Would a blacksmith or a road-mender be allowed to give evidence upon an abstruse problem in engineering? We think not. And yet this is a fairly parallel case.

HOSPITALS AND PUBLIC RESPECT.

AT a time when those who have the interest of hospitals at heart are trying to check the abuse to which they more than all other charitable institutions are subjected, it is to be regretted that anything should occur which might tend to lower the respect in which hospitals should be held by the general public. Last week at Wood-green a carnival was held in aid of a local hospital. This took the form of a long line of tradesmen's carts, decorated, and accompanied by a motor car, a fire-engine, and a procession of cyclists in fancy dress, while tableaux were also introduced into the programme. Most of the vehicles were tastefully adorned, and a similar complimentary remark can be made with justice concerning the masquerade attire of some of the cyclists, but there praise must cease. We have on more than one occasion deprecated street processions in aid of hospital charities altogether, but what we have now to say is new. We have never before observed an element of indecorum on the part of those joining in these processions, but this element was present at Wood-green, and did not tend to heighten the respect of the sightseers for the institution with which it was associated in their minds. For any of the carnivalists to appear "in that long white formless robe that makes all woman one" displayed perhaps a want of taste, but when some of the masqueraders proceeded to act in a suggestive manner—and that certain of them did so admits of no doubt whatever—the want of taste touched the confines of the indecent. The grotesque tableau which bore some resemblance to Mr. Luke Fildes's picture of "The Doctor" did not reflect any credit on its designers, nor was it calculated to make the public particularly ready to support a medical charity, or, indeed, to do anything but smile at a solemn death-bed, while a person in the garb of a hospital nurse was as great a libel as Miss Glory Quayle. It is quite natural that secretaries of hospitals should take advantage of every means in their power to fill the coffers of the institutions to which they are attached, and in certain neighbourhoods it may be found that this method of promenading the streets forms a good means to that end, but it is highly advisable that such shows, if they must be held, should be conducted decently and in order.

THE "MASSAGE-KIDNEY."

"WE have allowed the quacks to get the start of us in the application of electricity to therapeutics," said Dr. Anstie on a memorable occasion, and the same, we fear, must, with equal truth, be said of massage. An excellent resource when medically prescribed and scientifically applied, massage is not only hazardous but positively hurtful when, on the "every man his own doctor" principle, the prescription originates with the patient who puts himself in the hands of one or other of the "masseurs" whose knowledge of anatomy, physiology, and organic lesion is on a par with that of the bonesetter or herbalist of disastrous notoriety. For what happens when the unscientific "massage" in question is practised on the "patient" who most commonly invokes its aid? He is as a rule gouty. In this state the kidney, which in such patients every sound practitioner watches with peculiar vigilance, is seldom or never quite equal to its functions. The unqualified "masseur," however, commences operations, and in his ignorance of anatomy and physiological function goes ploughing away at muscles infiltrated with the uric acid poison, creating as much histolytic waste as a brisk six-miles walk, and calling on the kidney for an excretory effort quite beyond its powers. Prolonged from day to day and unmodified by circumstances, till the "course" (often for weeks) is completed, this practice is simply destructive to the already damaged kidney and the patient finds he has got rid of a certain amount of pain or acquired a comparative ease of movement at the expense of chronic renal incompetence and eventual uræmia. That such is a too common history is familiar to nearly all consultants, particularly if their *clientèle* is on the Continent, where massage is practised with more zeal than knowledge. So generally has that history come to be recognised that the "massage-kidney" is taking its place in pathological classification, while its production is a complication for which sound diagnosis and treatment are making due allowance. The moral of it all is that none but the regularly qualified practitioner should prescribe massage, and none but the regularly qualified masseur should practise it. Indeed, more than one "Bade-Arzt," rather than sanction the manipulations of self-styled "masseurs" on his patients, has gone to the headquarters of the art at Stockholm and there taken lessons in it so as, *faute de mieux*, to apply the said manipulations himself. To such a course, however, he only resorts when the duly qualified masseur, armed with the diploma of the Stockholm school, is not to be had. This is becoming an ever rarer contingency and at nearly all the better balneary establishments or "Kurörter" the Swedish

Digitized by Google

"diplomé," one or more in number and of both sexes, is attached to the institution. To this position the said "diplomé" has entitled himself by a systematic course of study not less than three years in duration—a course which comprises some anatomy and physiology and so much pathology as enables him to coöperate intelligently with the prescribing physician. To their credit be it recorded, the Swedes have created a school of massage on a sound basis and have reaped the reward in seeing their diplomés take rank with the "auxiliary forces" of the great army of medicine. In time, of course, their example will find effective imitation at other schools, with the result, peradventure, that "the pupil will excel the master." Meanwhile, the self-respecting practitioner at the great balneary centres abroad has come to be satisfied with none but such properly certificated "masseurs" and "masseuses." At home, when Parliament has put down "massage shops," the unwritten law of the profession will, we hope, make it soon impossible for any but scientifically-trained and medically-prescribed massage to find favour with the public.

A CHILD KILLED BY A MOTOR CAR.

THE motor car has taken its first toll of human life in London, a child, aged nine years, having lost his life through the agency of one in Hackney on Sept. 22nd. From the evidence given at the inquest it was perfectly apparent that the accident was in no way due to either recklessness on the part of the driver or to any defect in the machinery of the car. Deceased was one of a lot of schoolboys who ran after the car and amused themselves by getting on and off at the back. He was sitting next the driving chain and edged nearer to it to make room for a comrade. While so doing he was caught in the chain, twisted round and entangled in the wheel, sustaining fatal injuries. The foreman of the jury suggested that a network might be put over the chain, but the driver of the car was of opinion that "that would not last a week with the class of boys in the neighbourhood." We are inclined to agree with him; the London boy is perfectly reckless and daily escapes death by a miracle, witness the way in which he will board an omnibus when the conductor is engaged in collecting fares, and will jump off under the noses of the horses attached to the next vehicle without ever looking or thinking of the possibility of being run over. All we can hope is that this accident, lamentable as it was, will not prejudice the public against what promises to be a very useful method of locomotion, for it is evident that neither the driver nor the car was in fault.

HUNTINGTON'S CHOREA.

THIS curious disease, characterised by its appearance in adult life and by its tendency to affect several members of a family, to be inherited, and to end in insanity, is sufficiently uncommon to lend considerable importance to a paper in a recent number of *Brain* in which Dr. Michell Clarke describes some cases one of which ended fatally. He also describes the post-mortem condition of the nervous system found in this one. The first case was that of a painter, aged fifty-four years, a scheme of whose family history is given. From this it is seen that the patient's grandfather was twice married and had two children by his first wife and four by his second. Of these six children no less than four died insane, and one is known to have had chorea as well. Of the other two, one is living, aged eighty years, and suffers from chorea; the other died sane at the age of sixty years, but was prematurely aged-looking. The patient whose case is related is one of a family of three, the father being the fourth child who himself died insane and suffered from chorea. Of the other two one died in Fishponds Asylum. Of two cousins one died in an asylum, and the other is at present an inmate of Bath Asylum suffering from chorea and insanity. Of the next generation none seem to suffer as yet. There was nothing unusual in the patient's mode of life. The first symptom noticed was involuntary stamping of the right foot, followed by general twitchings. On his admission to hospital constant choreic movements were present in all the muscles of the trunk and limbs, the knee-jerks were active, and sensation, general and special, was normal. His memory was defective and inaccurate, but he had no delusions or hallucinations. The younger brother of this patient is Dr. Michell Clarke's second case. He was in Bristol Lunatic Asylum and had suffered from choreic movements for several years. He was demented and had delusions, but his memory and intelligence were fair. There was nothing noteworthy in the state of his bodily organs. The movements ceased entirely during sleep, although they affected the muscles of the face, trunk, and limbs. He died from pneumonia after a few days' illness. There was no very obvious naked-eye change in the nervous system, but careful microscopic examination of prepared sections showed widespread but partial degeneration of the cells of the cerebral cortex, especially those of the second and third layers, most marked in the frontal and motor convolutions, and an increase in the amount of interstitial tissue and of neuroglia cells. Dr. Michell Clarke also briefly relates another case of the same disease under his care in 1893. The family tendency to insanity in the case of this patient was not so marked, but his father had suffered from choreiform movements, and two sisters had been similarly affected. The illness began with loss of power in the legs, and when he came under observation all the muscles were agitated by constant spasms which ceased during sleep. Dr. Michell Clarke is of opinion that the cerebral cortex, especially the motor convolutions, is the seat of the disease, and that the change is a degeneration of cells with a concomitant increase in neuroglia. Similar changes have been observed in cases of ordinary chorea, and the identical nature of the spasms in the two conditions would seem to indicate a similar affection of the same parts of the nervous system in both cases. But from the greater severity and longer duration of the symptoms in Huntington's chorea the changes would naturally be expected to be more obvious in that disease. Dr. Michell Clarke's paper is illustrated by exceedingly good photo-micrographs of sections.

A ROYAL PHLEBOTOMIST.

A SHORT time before his death the Duc d'Aumale, who was one of the immortal forty, read a paper at a meeting of the French Academy entitled "Le Roi Louis Philippe et le Droit de Grâce." To a certain extent a dissertation on Royalism, this essay was likewise largely biographical, and by way of motto it bore the following words taken from Victor Hugo's "Les Misérables": "The first monarch who spilt blood to preserve life." The incident to which the poet makes allusion is thus described by the Duc d'Aumale: "On the 27th of October, 1833, my father, accompanied by the whole of his family, went to meet his son-in-law, the King of the Belgians, who was on his way to Paris to pay him a visit. I was one of the children who were packed together in the front of the *char-à-bancs*. The Brussels travellers were late, and accordingly, greatly to our satisfaction, we took the mail coach at Bourget. A luggage courier named Vernet, who was accompanying us, happened to get jammed by a cart, and was thrown from his horse under the wheels of the Royal carriage. They carried him to the edge of the road, where he was quickly surrounded by a crowd of people. The King at once made his way to the spot, and having examined the injured man and asked a few questions he exclaimed, 'Why, he must be

Digitized by Google

bled; is there anybody here who knows how to draw blood?' To this inquiry there was no answer, so my father took from his pocket a lancet which had not quitted his possession ever since the time when he used to act as a dresser at the Hôtel-Dieu, and of which he had made use during his American voyages, directed the attendants to tear up some handkerchiefs, set out his bandages, arranged his appliances, performed the bleeding, and applied the ligatures. The operation was a success. Vernet, who was no longer a young man, for he used to accompany the Emperor, was still running the mail ten years later."

MORALS AND THE STAGE.

SIR HENRY IRVING is much exercised by the remark of a speaker at the recent Sanitary Congress at Leeds that many crimes of violence were promoted by posters representing crimes as portrayed on the stage. At a complimentary banquet at Cardiff Sir Henry Irving asked how many wives had owed a violent death to the pernicious example of Shakespeare in *Othello*. We should doubt ourselves whether crime was ever prompted by either a poster or a stage representation. Indeed, to judge from the behaviour of the audience at Drury Lane Theatre, who greet Mr. Henry Neville with howls of execration, crime as represented on the stage exercises a most wholesome influence. The reading of "penny bloods" is no doubt deleterious, but at present we think the stage may be held innocent.

THE SANITARY STATE OF POONA.

Apropos of the late trenchant report of Surgeon-Major J. P. Barry on the breakdown of local self-government in India, as illustrated by the disgraceful state of Poona, owing to the neglect of the municipal authorities, the *Times* of Sept. 24th had some very wise and pertinent questions to ask. Poona is a place in which highly intellectual and educated Brahmins exercise a decisive influence, but where they have failed to discharge the most elementary duties that fell to their charge. As we all know, the educated classes in India are always asserting their claims to take part in the Government of that country, but their education has for the most part been such as to qualify them for theoretical and paper work rather than for really useful practical work. The native intellect and character are peculiar. The natives of Bengal have prodigious memories and good receptive faculties. The possession of these fits them for passing examinations upon subjects which they do not really understand and of which they have no practical "grip." They are children with subtle, casuistical minds; they will commit to memory examination text-books from cover to cover and write about subjects to any extent, but as to really knowing them objectively and usefully, or applying their knowledge with a practical end in view, that is quite a different matter; in fact, the education of the average Bengali youth is often only "shoddy" and veneer. Of course, there are very many exceptions. We are only speaking of the many—the average—who are puffed up with book-knowledge which they have not really assimilated, and this unfits them for any really useful work requiring earnest thought and genuine labour. It is doubtful whether the progress of sanitation in India has been really advanced by introducing a system of native self-government or local municipal authority. Money measures men in India as elsewhere; the native population is very poor and very averse to change of any kind or to the expenditure of rupees; and under such circumstances material progress is extremely difficult. Sanitation in India must advance slowly, for it presupposes education, and we cannot legislate much ahead of the feelings of the people without incurring grave unpopularity and risk of another kind. Lord Ripon's policy regarding local self-government in India has not by any means been so successful as philanthropic people anticipated. As an intelligent native once remarked: "Sahib, we pay you well to govern us and to do all these things for us, and now you want us to do it all for ourselves and govern ourselves." Be the cause what it may, the local municipal Governments of Poona, Calcutta, and Bombay have not proved satisfactory. Local bodies have no initiative; they will meet and talk and devise schemes on paper, and there it ends; they do not see that their schemes are practically applied, and vote the necessary funds for carrying them out. Epidemic diseases come in time, give rise to panic, an exodus of the native population, a Government inquiry, and expensive reforms. So it comes about that, as in the case of the city of Bombay, a large scheme of sanitary reformation has to be devised, and the work of carrying it out has to be entrusted by the Government to a nominated body which is independent of the corporation. In time it may be otherwise; that will be when intelligent and rich natives will put their hands to the work directly in front of them, for the good of everybody and to the great relief of an overworked Government.

"YOU MUSTN'T TOUCH."

A VERY old and very persistent superstition has again dictated the action, or rather the inaction, displayed by the persons who were the first to dicover the body of a recent suicide. A poor fellow, named Henry Scott, recently committed suicide in a Suffolk village by hanging himself to a tree. It was stated at the inquest that an hour before he was cut down a man saw him suspended from a branch, but that instead of ascertaining whether life was extinct he went for the police, being under the impression that a body must not be touched save in the presence of the police. Some children also saw the unfortunate man and ran to tell their elders. But their elders did nothing, being under the same curious impression. It cannot be too widely known that the prejudice against touching a body save in the presence of the police is founded upon nonsense, and nonsense to which before now lives may have been sacrificed. The fault probably lies at the door of the police who, in cases where a body has been moved and a verdict has been subsequently returned against some persons unknown, have been known to hint that if things had not been disturbed they could have obtained a clue—the sort of clue, we suppose, the absence of which accounts for the unsuccessful inquiries into the death of Miss Camp. The duty of a person who finds a body is first to ascertain that it is a body and not a fellow creature. If life remains a medical man should be sent for and afterwards the police. If it is necessary to remove the body to ascertain that it is a body—this would always be the case when dealing with death by hanging—it will of course be well to take accurate notes of the position in which it was found for the information of justice.

CROSSED ADDUCTOR JERK.

IN a recent number of the *Journal of Physiology* Dr. Purves Stewart has a short paper dealing with this subject. The peculiarity of a crossed jerk is one which is not unfrequently observed, and essentially consists in movement of the opposite leg when an attempt is made in the ordinary way to elicit the knee-jerk on one side. In Dr. Stewart's case if the right patellar tendon was tapped two jerks occurred, one of the right quadriceps extensor, the other of the left adductor muscles, and conversely of the right adductor muscles and the left quadriceps extensor when the left patellar tendon was tapped. The jerks of the two legs appeared to occur simultaneously, but an apparatus was devised to show (1) the moment at which the patellar tendon was tapped;

Digitized by Google

(2) the moment at which the knee-jerk occurred; and (3) the moment at which the crossed adductor jerk took place. The instrument is described in the paper, and three photographs are also reproduced of successful tracings taken during the experiments. These show clearly that the crossed adductor jerk occurs at an interval distinctly later than the knee-jerk, the average delay between the occurrence of the knee-jerk and the crossed adductor jerk in the three experiments being 0·057 of a second. This interval is considerably shorter than Dr. Glynn found in a case of crossed vastus internus jerk. Dr. Stewart mentions that different opinions have been held as to the nature of the crossed jerk, some observers considering that it is a true reflex, others that it is a direct muscular jerk produced by a sudden stretching of the adductor muscles resulting from the "jar" to the pelvis caused by the tap on the patellar tendon; others also hold that the adductor jerk is due to a sudden mechanical shock to the spinal cord. Dr. Stewart is induced, by a consideration of the results of his experiments, to conclude that the crossed adductor jerk is not the result of direct stretching of the adductor muscles by a shock communicated from the pelvis or due to a shock transmitted mechanically to the spinal cord, but is a true reflex occurring at a period distinctly later than the ordinary knee-jerk. The considerations which have chiefly led him to reject the two former views are that a tap on any of the bones near the knee, although equally likely to "jar" the pelvis, did not produce the jerk, and that only one adductor jerk was produced, and not one on the same side as well. He finds that the average time necessary for the appearance of the crossed adductor jerk is about 0·126 of a second from the time at which the opposite patellar tendon is tapped.

FOOD AT PUBLIC SCHOOLS.

AN animated correspondence under the above heading is being carried on in the *Morning Post*, and, as is usual in a newspaper discussion, the views of correspondents put forward two entirely opposite opinions. On the one side we have the delightful letter of "Quiz," who has two boys at Eton, and "upon my mentioning to one that people had been writing saying that boys were not sufficiently fed he remarked, 'Oh, golly, what a lie!'" Here we have one side of the shield. The other is exemplified by the horrifying letter of "A Mother of Four Sons," who sent "one of my boys a large package of mulberry leaves for his silkworms, and he told me afterwards that he had been glad to eat most of the leaves himself, for he got no vegetables, and the craving for green food was intense." Now we do not doubt in the least that the boy said this, but we very much doubt the craving for green food, for the average boy resembles the gentleman quoted by, we fancy, Surtees, in one of the Jorrocks' books, who upon being offered watercresses replied: "Do you take me for a rabbit?" As to the *menu* at public schools nowadays we cannot speak with certainty, but some twenty-five years ago we can say from personal experience of one school that though the food as a whole was good, and there was plenty of it, it was served out at the wrong time. Before going into early school in the winter coffee and bread were provided; breakfast, at 8.30, unless supplemented by the boys' own resources, consisted of tea or coffee and two under-baked rolls. Nothing more was provided till 2 P.M., when dinner was served, both plentiful and good. Tea, at 6 P.M., was a *résumé* of breakfast, and at nine there was supper if anyone liked to have it, consisting of meat, salad, or other "green food," bread, butter, cheese, and beer. As a whole, then, the quantity of food supplied in twelve hours was ample, but it would have been much better to have supplied the meat with breakfast and not at supper. For a boy to fill his stomach with meat and beer just before going to bed is most harmful, and it is almost equally harmful to expect a growing boy to work his mind and body in various forms of mental and physical exercise from 7 or 7.30 A.M. until 2 P.M. upon nothing but coffee and bread-and-butter. We should imagine that, as "Quiz" also points out, sanitary matters and ventilation are in more need of reform than food.

RESPONSIBILITY FOR INSANITARY CONDITION OF HOUSES.

A RECENT decision given by the Recorder of Belfast (as reported by our correspondent) shows the peculiarities of the law. According to this authority, and he gave judgment accordingly, if a citizen takes an unfurnished house he does so with his eyes open; if it is not in a sanitary condition he must examine it, and if it is defective from a sanitary point of view he must, at his own expense, make it right. Neither the landlord nor the agent was bound to do so. On the other hand, the Belfast Recorder laid down the law that if the house was furnished that fact implied that it was fit for habitation, and those letting the premises under such conditions were bound to make them sanitary in all respects. Notwithstanding this decision, we think that no person should take a house, whether furnished or not, unless those letting the premises are willing, if required, to allow an examination of the house as to its sanitary condition to be made by an independent authority. If the house is found to be defective it should be made right by the landlord, who should pay the sanitary engineer for his examination. On the other hand, if the premises are in a correct sanitary state the tenant should pay for the examination.

THROMBOSIS OF THE JUGULAR VEINS.

THROMBOSIS of the large veins of the neck is a condition of great rarity if we can judge by the recorded cases, which number only twenty. In the *Journal of the American Medical Association* for August, 1897, Dr. Helen Baldwin describes the following case. The patient was a girl, aged nineteen years. Five weeks before admission to hospital she noticed swelling of the feet, which gradually increased, and a few days previous an aching pain developed in the left axilla and in the left side of the neck. There was also swelling in the neck, which at first would disappear when she sat up and reappear when she lay down. The patient had suffered from rheumatic fever in childhood, and was troubled with tachycardia whenever she exerted herself. For several years she had not been strong. On admission she appeared very weak, and cyanosis and dyspnœa were present. The lips were livid and the veins of the nose dilated. The pulse was small, rapid, and compressible. There were double mitral and aortic murmurs and the heart was much enlarged. On the left side of the neck was a hard, tender swelling formed by the lower part of the external jugular vein. There was a hard lump in the left axilla extending down the arm for about five inches. The arm was œdematous and pale, not cyanosed. On the next day the left external jugular vein could be felt as a cord running up the neck, which was fuller on this side. The patient died from heart failure on the seventh day. A necropsy showed thickening of the aortic valves, thickening and adhesion of the mitral valves, and congestion and pneumonic changes in the lungs. The left innominate, subclavian, external and internal jugular veins were thrombosed. In the subclavian vein there was endophlebitis, which evidently, in conjunction with the feeble circulation, caused the thrombosis. An analysis of the cases of thrombosis of the jugular veins reveals the following facts in regard to the etiology. In nearly a fourth of the cases there was pressure on the vein often from a malignant growth. In nearly half there was a

Digitized by Google

grave blood dyscrasia—malignant disease, tuberculosis, syphilis, pyæmia or acute rheumatism. In five there was endophlebitis—rheumatic, syphilitic, or traumatic. In a third the condition was secondary to middle-ear disease. The prognosis is bad; the condition is seldom found except in the last stages of fatal diseases.

GUN ACCIDENTS.

THE bicycle and the gun seem to be at present vying with one another as to which shall kill or injure the greater number of people, but with this important difference, that whereas the one who injures himself or loses his life in a bicycle accident has, as a rule, only himself to blame, the death or injury of anyone from a gun is almost invariably due to the idiocy of someone else. From a list of various gun accidents reported in the daily press we select the following as an example. At Puckeridge, Herts, a medical man went out shooting with a friend, and on arriving home the friend left his gun in the carriage. A page boy took it out, and while carrying it across his arm it went off and shot a servant, inflicting fatal injuries. As to whether blame or not is to be attached to the boy we cannot say—this will never be known, for the only possible witness is dead—but it was certainly an act of the very greatest carelessness to leave a loaded gun in the carriage, and we cannot help rejoicing that it was not the medical man who acted thus. To carry the loaded gun whilst driving was courting death. Another sad death due to someone's carelessness occurred at Manea recently, when a child, aged four years, was shot by his brother with an old rusty gun found by the lad in the washhouse. The boy did not know that the gun was loaded, and we are not told whether he levelled it at the deceased or not; but it went off and killed the child. The responsibility for this death lies primarily at the door of the person who left the loaded gun where it was accessible to the children.

THE WORSHIPFUL COMPANY OF PLUMBERS AND THE CITY AND GUILDS OF LONDON TECHNICAL INSTITUTE.

JUDGING from the recent correspondence in the *Pall Mall Gazette* there is a sad absence of unity between the company and the institute, which is the more remarkable in that both bodies are professedly working with one object—viz., to increase the proficiency of the artisan. As is well known, the Bill promoted by the company for the registration of plumbers met with a good deal of organised opposition last session in the House of Commons and was unfortunately lost. An anonymous letter in the *Pall Mall Gazette* accuses the Institute, in which Sir Philip Magnus holds the post of superintendent of technological examinations, of organising this opposition to the Bill, because the company refuse to grant their diploma to individuals passed by the examiners of the institute, the company's objection being that the candidates of the institute are not submitted to any practical tests. If the statements circulated by our contemporary are correct, the action taken by the institute in connexion with the Plumbers' Registration Bill is much to be regretted by all interested in sound sanitation. The term "paper plumber," of which a good deal has been heard lately in connexion with examinations embracing theory only, has by no means an assuring sound. The public would be interested in hearing that there is no truth in these damaging statements. Unfortunately, Sir Philip Magnus does not see his way to do more in reply than to refute the matter in general terms. He is more concerned about some side issue as to the reputation of the Plumbers Company, for which anxiety, however, the company by their letter do not seem to be particularly grateful. If a public body like the institute undertake to grant a diploma to plumbers the public have a right to expect that such diploma is a guarantee, not of theoretical knowledge only, but of practical work also, without which latter the former is useless.

LONDON POST-GRADUATE COURSE.

ON Monday next (Oct. 4th) a daily course in practical bacteriology will commence at King's College, and will continue for six days. The winter session will commence on Oct. 11th, and will last for eight weeks. Classes will be held at the following hospitals and institutions—viz., in skin diseases at Blackfriars Hospital; diseases of the mind at Bethlem Hospital; diseases of the throat, nose, and ear at the London Throat Hospital; practical bacteriology at King's College; general medicine and surgery at the Central London Sick Asylum; hygiene and public health at the Parkes Museum; and in urine testing at the Institute of Preventive Medicine. Practitioners can attend all the classes during the term or can take out any class they select. They can enter for one or more weeks or all the courses as suits their convenience. All information can be obtained from the secretary, Dr. Fletcher Little, 32, Harley-street, W.

ANKYLOSTOMIASIS IN ASSAM.

A CORRESPONDENT who has been long resident in Assam, and is familiar with the conditions under which the coolies live in the tea gardens there, informs us that assuming all the deaths entered as due to dropsy and anæmia to be caused by ankylostomiasis, there were only 731 fatal cases coming under this head among a total of 5656 deaths occurring in 143 gardens recognised as being unhealthy. There is, however, another side to this question. Ankylostomiasis is not only not necessarily fatal, it is not even actually injurious to a man in otherwise fair health and living under normal conditions, but if a person infested by the parasite is brought to the malarious climate of Assam, and there contracts fever or dysentery, he collapses at once, rarely recovers his strength, and drags on a miserable existence for the rest of his life. Our correspondent goes on to quote from the Annual Report of the Sanitary Commissioner with the Government of India for 1892, in which Surgeon-Major E. Dobson, civil surgeon of Dhubri, stated that among 547 of the healthiest-looking of the coolies who arrived at Dhubri with the intention of executing labour contracts in Assam, ankylostoma were present in 454, or 83 per cent.; he found the parasite in persons newly arrived from Bengal, Behar, Orissa, Chota Nagpore, the Central Provinces, the North Western Provinces, the Punjab, Madras, and Nepal. Both sexes, at all ages, Hindu and Mohammedan alike, harboured the parasite without apparent ill effect. The sanitary commissioner also remarked: "From the reports furnished by a number of medical officers of the tea gardens, it appears that the chain of symptoms described as ankylostomiasis does not usually develop until some months after arrival in Assam." He, moreover, adds that the following conclusions seem justified: "1. The presence of the ankylostomum in the intestines does not necessarily give rise to serious symptoms unless other circumstances favour this result. 2. The presence of the ankylostomum in the intestines may be a serious complication, but is not the cause of Ká'á ázár. 3. The so-called beri-beri of Ceylon and Assam has no connexion with the disease known by this name (the signs and symptoms of which are chiefly due to the effects of peripheral neuritis) which occurs in the Dutch East Indies, Hong-Kong, the Straits, and occasionally in Burmah; it is probable that this disease rarely, if ever, occurs in Assam." Dr. Shand, the medical officer of the Jorehat Tea Company, has also found that patients who were in a very bad state

Digitized by Google

improved rapidly as soon as they were freed from the ankylostoma by the thymol treatment and placed on tonics and good diet.

"FINEST IRISH HAMS."

ON Sept. 27th sundry fraudulent tradesmen received at Richmond Police-court, we will not say their deserts, but an inadequate punishment for deceiving customers. Their names were Messrs. Coppin Brothers and two assistants, Messrs. Meslin and Wheeler; Mr. Dunkin, the manager of Messrs. Williamson and Co., and an assistant, Mr. Simpson; Mr. James and his assistant, Mr. Lewis; Mr. Batchelor and his assistant, Mr. Lampsard. Inspector Moore asked for a Scotch ham and was supplied with one which was entered on the invoice as Scotch. On Mr. Moore mentioning who he was Mr. Meslin promptly admitted that the ham was American. Mr. Coppin was fined £5 and the assistants 10*s.* each. Messrs. Williamson sold an American ham as a Bath ham, and the assistant averred without contradiction that he had been told to say they were Bath hams. Mr. Dunkin, the manager, was fined £5 and the assistant 10*s.* Mr. James's case was specially flagrant. He exhibited a large placard with the words, "Finest Irish Hams, 9*d.* per pound," but Inspector Ward having bought one he was refused permission to see the invoice, and Mr. James admitted that the ham was American. He was fined £10 and his assistant 10*s.* In Mr. Batchelor's case the fine was £5 and in the case of the assistant 10*s.* In the report of the Select Committee on Food Products Adulteration it was suggested that offenders should be required to publish at their own expense a notice of their conviction in the public journals of the locality in which their places of business were situated or in any other such way as might be thought desirable to give due publicity to the conviction. This excellent method of punishment would be admirably fitted for such instances of fraud as those just described and would no doubt put an end to this deceitful practice. But the public are much to be blamed in this matter. They place implicit trust in the tradesman, and believe that he can supply them with a superior article at a very low figure, or at any rate at a price at which it must be well known the superior article cannot possibly be supplied. It is this blindness on the part of the public which encourages tradesmen to palm off various articles under a fraudulent description.

A GENERAL meeting of the Medical Society of London will be held at 11, Chandos-street, Cavendish-square, W., at 8 P.M., on Oct. 11th, to receive the treasurer's report and balance-sheet as passed by the auditors. The President having vacated the chair, the new officers will commence their duties, and an ordinary meeting of the society will be held at 8.30 P.M., when the incoming President, Dr. A. Ernest Sansom, F.R.C.P. Lond., will deliver the opening address on "The Investigation of Some of the Nervous Disturbances of the Heart." After this a paper will be read by Mr. William Anderson, F.R.C.S. Eng., on "John Arderne, the Father of English Surgery, and his Time.

THE ROYAL VICTORIA HOME, BRISTOL.—This Institution, founded through the efforts of some charitable people about a year ago, is doing useful work. Its objects are to provide a home for poor inebriate and other women and for deserving female offenders. Such of these as are unmarried are trained for domestic service and all are instructed in housewifery generally. The home is licensed both under the Inebriates Act and by the Home Secretary. It is well known that the atmosphere of a prison is not conducive to reformation, and an institution of this kind is often the means of setting those who have yielded to temptation in the right way again.

THE VACANCY IN THE GENERAL MEDICAL COUNCIL.

SINCE our last issue the position has somewhat changed, inasmuch as Sir Walter Foster, M.P., has entered the lists. We publish Sir Walter Foster's address to the profession below, and also an account of a meeting held on Wednesday afternoon last in support of his candidature.

Mr. George Jackson asks us to announce that he has retired from his candidature as a Direct Representative on the General Medical Council in favour of Sir Walter Foster, whom he considers to be "a candidate who is well worthy of our support. He will oppose any attempt to create an inferior order of practitioners by throwing the ægis of registration over the midwives, and, I believe, is the strongest candidate all round that we can have at the present time." Mr. Jackson also wishes to thank all those who had promised to support him.

Dr. R. R. Rentoul also sends us a letter for publication, in which he asks "all practitioners to record their vote in favour of Sir Walter Foster."

We have received a great number of letters urging the merits of the different candidates, a large proportion of which have not hesitated to point out also their demerits. We need hardly say that in the latter case we have given preference to those which are temperately written and signed in full. From these letters we think it is imperative that Sir Walter Foster should make a clear and full explanation to the profession of the circumstances under which the unfortunate and unfortunately-worded interview in the *Young Man* came to be published.

A communication signed by Dr. J. Rees Gabe and Mr. R. B. Anderson (London), Mr. George Jackson (Plymouth), Mr. Joseph Smith (Chiswick), and Mr. W. G. Dickinson (Putney) has also been sent to us. It contained a copy of a letter which has been addressed by these five gentlemen to all the candidates, enclosed in which is a series of questions upon which the candidates are invited to express their opinions. Before publishing these questions we prefer to wait until we have received from the writers of the letter information as to the replies they have received.

Dr. Hugh Woods, President of the Incorporated Medical Practitioners' Association, asks us to publish in THE LANCET the following resolution which was unanimously passed at a meeting of the Council of the Association held on Tuesday last:—

"The Central Council appreciates the motive of Mr. George Jackson's withdrawal as a candidate at the present election of a Direct Representative on the General Medical Council. Having heard Sir Walter Foster's letter to the Chairman of this Council, and having regard to the invaluable services rendered to the medical profession by Sir Walter Foster in his ten years' tenure of office as a Direct Representative, and to the fact that he supports the programme of this association, the Central Council strongly recommend that the active support of the members of this association should be given at this election to Sir Walter Foster."

At a meeting of the Medico-Ethical Association of North-East London, to be held to-night (Friday, Oct. 1st) at 9 P.M., at 184, Mare-street, Hackney, Mr. Victor Horsley will read a paper on Medical Reforms.

On the afternoon of the same day at 5 P.M. a meeting will be held in support of Mr. Victor Horsley's candidature at the Medical Society's rooms, 11, Chandos-street. On the following day (Saturday, Oct. 2nd) there will be a meeting at Norwich at 4.15 P.M. in the library of the Norfolk and Norwich Medico-Chirurgical Society, Guildhall-hill, Norwich, with a similar object.

SIR WALTER FOSTER'S ADDRESS.

TO THE REGISTERED MEDICAL PRACTITIONERS OF ENGLAND AND WALES.

LADIES AND GENTLEMEN,—On my return from Canada to-day I found many letters from valued friends urging me to become a candidate for

Digitized by Google

the vacancy on the General Medical Council caused by the regrettable resignation of Dr. Rentoul. Others whom I have consulted strongly press upon me the same course, and I have therefore decided that in the present crisis of Direct Representation it is my duty once again to offer my services to my professional brethren.

My experience of the struggles during recent sessions of Parliament in connexion with the Public Health (Scotland) Act and the Midwives Registration Bill has also influenced me, as I am convinced that the most watchful care must be exercised by someone authorised to speak for the profession in order to prevent legislation alike hurtful to the public and hostile to the profession.

The ten years' service which I gave to the Council is the best guarantee of the spirit in which I should, if honoured by your confidence, again take up the work.

As in the past, I am prepared to advocate:—

1. The increase of the representative element on the Council.
2. The maintenance of a high standard of professional education, an increase of the requirements of the preliminary examination, and the establishment of one uniform qualifying examination for each division of the kingdom.
3. The more vigorous exercise of the existing powers of the Council for the suppression of improper and irregular modes of practice and for protecting the public from unqualified persons and quacks.
4. The amendment of the Medical Acts in such a way as to strengthen the powers of the Council and more effectively protect the interests of the general practitioner.

While anxious to improve the education and training of midwifery nurses, I am resolutely opposed to any legislation which would register women as midwives and enable them to practise midwifery without the superintendence of a registered medical practitioner. I have fought this battle in the interests of the poor and in support of the general practitioners now for some years, and I hope it may be my privilege as your representative to carry the struggle to a successful issue.

I am, your obedient servant,

Birmingham, Sept. 23rd. B. WALTER FOSTER.

SIR WALTER FOSTER'S CANDIDATURE.

The room in which the Medical Society holds its meetings at 11, Chandos-street, Cavendish-square, was very full on Wednesday afternoon last when Sir Walter Foster, M.P., made a statement with respect to his policy as a candidate for the General Medical Council.

The CHAIRMAN (Dr. Leonard W. Sedgwick), in calling upon Sir Walter Foster, quoted from Mr. Victor Horsley's election address the opinion that "the prospect of advancing medical reform depends more upon the previous training of the representatives than upon the fact of their belonging to one particular section of the profession," and said that Sir Walter Foster had both the training and an accurate knowledge of the Medical Acts.

Sir WALTER FOSTER thanked those present for coming to the meeting. It was, he thought, the largest gathering that had ever been held in any part of the United Kingdom for the purpose of listening to the address of a candidate for the General Medical Council as a direct representative. He had come forward at the present time because he believed there was an exceptionally grave crisis in the history of direct representation. Since his resignation the expressions of regret from the profession that he had severed his connexion with the General Medical Council had been so frequent that he felt these expressions were almost reproaches. On his return from Canada he found many telegrams and letters awaiting him, urging him to become a candidate for the present vacancy. Under the circumstances, being comparatively still a young man and remembering what he owed to the medical profession, he thought it would be wrong of him if he did not come forward and do what he could in the interests of the profession. His present policy was very much the same policy as that which had guided him when he last had the honour of representing the profession on the Council. He referred to his stand for the profession as against the Corporations, his efforts for the suppression of covering, and his desire for increased direct representation. He was also anxious to get back to the General Medical Council because he felt that the state of the general body of the profession was most serious. Never had he known it so overcrowded or put to such shifts on account of irregular practice, hospital abuse, and medical aid associations. The general practitioner had a much harder lot than he had thirty years ago. While the expense of training was greater in the actual battle of life competition was most severe. He wanted to improve that state of things. In one respect these evils would be overcome by raising the standard of the preliminary examination. A little more care and scrutiny on the part of the Council might do something practical for the other evils. With regard to the midwifery question, he said he had never been opposed to the proper education of women who attend midwifery cases as nurses, but he was absolutely opposed to any legislation which would register women as midwives and enable them to practise without the superintendence of a registered medical practitioner. He would not be a party to the sanctioning of any Bill which would enable them to attend the so-called cases of natural labour which were never natural till they were safe, and which no man could define till they were over. He would oppose such legislation on two grounds—first, its contravention of the Medical Acts, and, secondly, on the ground of its injury to the poor and the profession. He concluded by referring to the action he had taken in endeavouring to strengthen the hands of the Council in dealing with penal cases, and expressed his willingness to serve the profession in the future as he had done in the past ten years on the Council if the profession would give him their confidence.

In answer to questions by Dr. HUGH WOODS, Dr. ALDERSON, Dr. BATEMAN, Mr. CREASY, Mr. STANLEY BOYD, and others,

Sir WALTER FOSTER said the Universities elected their own representatives on the General Medical Council, and he did not think it was within the powers of the Council to say how those elections should be made, but he would be prepared to raise the question whether such representatives were properly elected. No one had called his attention to the fact that the Bill of 1886 had taken from medical men holding British qualifications the right of practising in any part of the British dominions, but in other ways he had amended the Bill for the professional good. He did not practise in London, and though he lived there part of his time had no name on his door-plate. He had assisted to increase the curriculum to five years and he was in favour of re-establishing the system of apprenticeship. He concluded by giving the reasons for his previous resignation and by remarking that every man who was required to give a certificate by the Legislature should be paid for the same.

Dr. CLEVELAND moved: "That this meeting, having heard Sir Walter Foster's statement, expresses its confidence in him, and promises to use its best efforts to secure his return as one of the Direct Representatives on the General Medical Council."

Dr. WALLACE seconded the motion.

Dr. BATEMAN, apologising for introducing the matter, and remarking that members of the General Medical Council should be beyond suspicion, directed attention to an interview with Sir Walter Foster particulars of which had appeared in the October issue of the *Young Man*. This he characterised as a professional advertisement. He moved the previous question.

Dr. RISIEN RUSSELL seconded.

Sir WALTER FOSTER, in explaining the matter, said he in some respects had the misfortune to be a public man as well as a doctor, and a public man was occasionally interviewed. He went on to explain how the published interview had arisen from a conversation which he had had in a railway-train with a gentleman, and he had only given permission for the publication of the interview under the belief that it was solely for political purposes. He was sorry that any reference should have been made to his profession in the printed interview, but the article was published while he was away in Canada, and on his return he had seen the editor of the magazine and requested him either to withdraw the paper from circulation or to delete the objectionable matter. With regard to the photograph of his consulting room and the representation of the sphygmograph Sir Walter Foster said that it was not supplied for the purposes of the article, but was one that had been taken some years ago for illustrating a series of articles on the magistrates of Warwickshire.

The motion for the previous question being lost the resolution was carried by 54 votes to 10.

Many of those present abstained from voting.

THE INDIAN RISING.

THERE are many people who, drawing their conclusions from the latest items of intelligence, seem to think that the neck of the tribal insurrection on the North-West frontier has been broken and that the rising promises to come to a speedy and premature collapse. So far as the Mohmands are concerned this is probably the case, for they are as a rule a faint-hearted tribe as far as fighting goes; but the Afridis and Orakzais have still to be dealt

Digitized by Google

with, and the expedition against them is only just beginning. These tribes are a sturdier race—they are a more courageous, treacherous, and wily enemy. Although we entertain no doubt as to what will be the result of Sir William Lockhart's expedition against them it will involve a good deal of expense and difficulty, as well as probably a good deal of hardship and fighting on the part of our troops before the campaign is brought to a successful termination and a durable peace is obtained. The plan of the Tirah expedition has now been settled. Major-General Blood's force, with its three brigades, will remain in the Mohmand country in order to protect General Lockhart's flank from attack and to cut off, at the same time, the Afridis from the tribes in the north, leaving General Lockhart's force free to march to Tirah and promptly deal with the Afridis. The General's force for this purpose will be composed of regiments collected on the frontier in and about Kohat, and the expedition will start about Oct. 9th. The Mohmands seem to have fought sharply and well against General Jeffreys' brigade, and to have succeeded in inflicting some loss and a very brief temporary check to its successful progress; but the general result of the fighting that has taken place up to the present time has been success—and brilliant success—to the British forces. The devotion and gallantry of the natives have been conspicuous features. The health and spirits of the troops are reported to be good, and the sickness has not been at all great. The wounded are progressing favourably. As the season advances the conditions will become more and more favourable to the expeditionary force advancing against the tribesmen. No adequate explanation has yet been given of the reason for this general rising. It is probable that there was no single cause but that many factors were at work. The "forward policy" in Chitral could hardly have been the sole cause, for the tribes there have remained quiet. There has been an extended outbreak of fanaticism excited by the Mullahs, and it is probable that the recent successes of Turkey have not been without some influence as regards the rising at this time.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On Diphtheria in the Holywell Parishes, by Dr. F. ST. GEORGE MIVART.—The area about the Dee estuary has, by reason of disease and faulty administration, received an exceptional amount of attention from the Local Government Board; indeed, since 1871 there have been no less than ten visits of medical inspectors, the one preceding Dr. Mivart's inspection being recorded in the exhaustive report by Dr. Bruce Low on sewage pollution of the Dee. But diphtheria in the Holywell urban and rural parishes was the immediate cause of the present report, and Dr. Mivart at the beginning recalls the fact that a fatal cynanche, which was doubtless the same disease, can be traced back at least as far as 1794. In the urban parish much of the water-supply is exposed to pollution; the drainage arrangements are the same faulty ones that have been described by previous inspectors; and as to the disposal of excreta and refuse, matters are stated to be as bad, if not worse, than they were twenty years ago. The dwellings are also often thoroughly bad, decay and unfitness for habitation being their prominent features. In the rural parish of Holywell the dwelling accommodation is also most faulty, natural decay being at times the only cause that leads tenants to vacate the cottages. Many are built back-to-earth or back-to-back; conditions which, when associated with overcrowding, are typical of those which conduce to the maintenance and spread of a disease such as diphtheria. In one cottage access to the bedroom above was obtained by climbing up an inverted table; in "two rows of hovels," each of one room only, there was no back ventilation, and three feet from them in front was an excavated hill. Added to such conditions we read also of the surrounding land being in places water-logged and sewage-logged. There has, however, been improvement in the water-supply, notably in Bagillt; and the rural council have spent money in drainage works, some of which have unfortunately turned out badly. This is the more to be regretted because it may postpone the abolition of conditions to which the strongest adjectives descriptive of revolting filth are properly applied. The diphtheria in the urban parish was somewhat restricted; it was associated in its spread with a board school, and with the failure to check it by such methods as disinfection and isolation, and it spread a good deal in families. In the rural parish 183 cases had been notified in the eleven months ending November, 1896, and 22 cases had terminated fatally, besides which it seems clear that a number of minor attacks had escaped notice. Certain schools were closed, and both bedding and clothing were destroyed; but apart from a few such measures no energetic action was taken by the local authorities, who have, notwithstanding previous warnings, remained without any proper means for isolating or controlling infectious disease. Districts like this are the black spots on our country's record of improved sanitary administration; and until the inhabitants of such localities learn the value of human life and of health, and give proof of it by sending to their urban and rural councils those who will make public health a first consideration, it seems well-nigh useless to offer them advice and to make recommendations for their adoption.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Sheffield Urban District.—Dr. Harvey Littlejohn, who has recently relinquished his post as medical officer of health of Sheffield, reports that the estimated population of the city at the middle of 1896 was 347,278. The general death-rate for 1896 was 19·3 per 1000, the rate having only on one prior occasion—i.e., 1894—fallen below 20 per 1000. Infantile mortality was also small for Sheffield, being 171 per 1000 births, the average for the last ten years being 178 per 1000 births. Good results seem to have accrued as regards control of measles by the coöperation of the School Board authorities with those of the sanitary department, a notification being sent to the medical officer of health of such children as were suspected of being absent from school owing to measles, and similarly the sanitary authority furnished the school-master with a certificate when the invaded house was free from infection. Plumbism caused but three deaths, all of which were of file-cutters, in Sheffield in 1896, as against 5 in 1895 and 9 in 1894. Dr. Littlejohn thinks, however, that only a small proportion of the deaths primarily attributed to lead poisoning are certified as such in the death certificate, the intercurrent affection which kills the patient masking the primary cause. Dr. Littlejohn bases this opinion upon the extensive prevalence of lead poisoning among workers in the trade. There are but 200 beds provided in Sheffield for the isolation of infectious disease, a number which, as Dr. Littlejohn points out, is quite inadequate for a population of some 350,000. While taking care to provide adequate accommodation for the poorer classes the corporation should, it is urged, consider the question of providing suitable accommodation for the wealthier classes, who could easily afford to pay for it. Although there is perhaps from a public health standpoint less necessity for the isolation in hospital of cases occurring in houses where some sort of home isolation is possible, there can be no question as to the enormous boon which hospital accommodation is to the wealthier classes. In London, for instance, this class has the accommodation of the London Fever Hospital and of the Mary Wardell Convalescent Home, and anyone who has suffered from a prolonged attack of scarlet fever may have learnt to value these institutions. Dr. Littlejohn has for the last five years endeavoured to persuade the Sheffield sanitary authority to provide a public abattoir, but unfortunately on his leaving Sheffield this desirable addition is still *in nubibus*. In years to come we shall look back with astonishment upon the fact that Sheffield, and, for the matter of that, other large towns, did not in the year 1896 possess this most elementary provision against the sale of diseased and unwholesome meat. Among the advantages to be derived from public slaughter-houses Dr. Littlejohn mentions the prevention of unnecessary cruelty, and the detrimental moral effect which the sight of animals being slaughtered has upon the young. It is certainly most desirable to prevent this, and we have ourselves seen crowded around the windows of a slaughter-house during the hours of slaughter groups of children anxious to witness the killing process.

Essex County District.—Infantile mortality will, Dr. Thresh thinks, remain practically undiminished until the

Digitized by Google

simple laws of the preservation of health and of the necessities of infant life are taught, especially to girls, in the higher standards of our elementary schools. A certain amount of false delicacy is, we suspect, a formidable obstacle in the carrying-out of this suggestion. In the matter of infectious disease Dr. Thresh records the decreased prevalence of diphtheria throughout the county, and this fact is the more interesting inasmuch as Essex has figured very prominently in the past for its excessive diphtheria death-rate. We note in Maldon Urban District that a case of diphtheria was associated with the unloading of offensive London manure, while another case was thought to have derived infection from a cat. Unfortunately from a view-point of scientific interest the pharynx and larynx of the cat were not sent to Dr. Thresh for bacteriological examination. Where there is a county medical officer competent to make bacteriological examination it is well for the district medical officers of health to be alive to the opportunities thus afforded them. Typhus fever was hardly to be expected in the present day in the rural districts of Essex, but two patients were diagnosed as suffering from this disease in the Dunmow Rural District. No attempt has been made to put Part III. of the Housing of the Working Classes Act into operation in Essex, and Dr. Thresh thinks that until some arrangement is come to for providing money from a county or imperial fund labourers' cottages will not be erected. The systematic inspection of districts does not appear to have received as much attention as it should do. Without such systematic inspection there cannot be that seeking out of nuisances which is so much insisted upon by the Local Government Board. In Southend, where a house-to-house inspection is in progress, 73 per cent. of the drains in one street were found to be defective.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6176 births and 3600 deaths were registered during the week ending Sept. 25th. The annual rate of mortality in these towns, which had declined in the six preceding weeks from 29·5 to 18·5 per 1000, further fell last week to 17·1. In London the rate was 15·7 per 1000, while it averaged 16·0 in the thirty-two provincial towns. The lowest rates in these towns were 10·3 in Birkenhead, 10·4 in Swansea, 11·2 in Plymouth, and 13·7 in Brighton; the highest rates were 21·3 in Sunderland, 22·3 in Manchester, 22·4 in Sheffield, and 22·5 in Liverpool. The 3600 deaths included 607 which were referred to the principal zymotic diseases, against 945 and 721 in the two preceding weeks; of these, 327 resulted from diarrhœa, 75 from diphtheria, 57 from "fever" (principally enteric), 54 from measles, 51 from whooping-cough, and 43 from scarlet fever. No death from any of these diseases was recorded last week in Croydon or in Plymouth; in the other towns they caused the lowest death-rates in Birkenhead, Swansea, and Halifax; and the highest rates in Wolverhampton, Hull, Burnley, and Preston. The greatest mortality from measles occurred in Preston and Burnley; from scarlet fever in Leicester and Gateshead; from "fever" in Derby, Hull, and Bolton; and from diarrhœa in Liverpool, Hull, Preston, and Wolverhampton. The mortality frrom whooping-cough showed no marked excess in any of the large towns. The 75 deaths from diphtheria included 45 in London, 4 in Birmingham, 3 in West Ham, and 3 in Leicester. No fatal case of small-pox was registered during the week under notice either in London or in any other of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital, which had been 3528, 3579, and 3653 at the end of the three preceding weeks, had further risen to 3697 on Saturday last, the 25th ult.; 358 new cases were admitted during the week, against 376 in each of the two preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 116 and 113 in the two preceding weeks, rose again last week to 165, but were 11 below the corrected average. The causes of 30, or 0·8 per cent., of the deaths in the thirty-three towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Cardiff, Manchester, Bradford, and in sixteen other smaller towns; the largest proportions of uncertified deaths were registered in Leicester, Nottingham, Liverpool, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the three preceding weeks from 18·1 to 19·4 per 1000, declined last week to 17·8, but exceeded by 0·7 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 14·0 in Paisley and 15·1 in Aberdeen to 18·7 in Edinburgh and 22·0 in Greenock. The 532 deaths in these towns included 35 which were referred to diarrhœa, 20 to whooping-cough, 9 to "fever," 6 to scarlet fever, 5 to measles, and 3 to diphtheria. In all, 78 deaths resulted from these principal zymotic diseases, against 98 and 101 in the two preceding weeks. These 78 deaths were equal to an annual rate of 2·6 per 1000, which was 0·3 below the mean rate last week from the same diseases in the thirty-three large English towns. The 35 fatal cases of diarrhœa showed a further decline from those recorded in recent weeks, and included 11 in Glasgow, and 6 in Edinburgh. The deaths from whooping-cough, which had been 15 and 17 in the two preceding weeks, further rose to 20 last week, of which 13 occurred in Glasgow and 4 in Dundee. The 9 deaths referred to different forms of "fever," corresponded with the number recorded in the preceding week, and included 5 in Glasgow and 2 in Edinburgh. The fatal cases of scarlet fever, which had declined in the three preceding weeks from 10 to 2, rose again to 6 last week, of which 5 occurred in Edinburgh. The 3 deaths from diphtheria were below those recorded in any recent week, and included 2 in Edinburgh. The deaths referred to diseases of the respiratory organs in these eight towns, which had been 78 and 96 in the two preceding weeks, were again 96 last week, and exceeded by 40 the number in the corresponding week of last year. The causes of 25, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 22·4 and 23·9 per 1000 in the two preceding weeks, further rose to 28·3 during the week ending Sept. 25th. During the past twelve weeks of the current quarter the death-rate in the city has averaged 23·8 per 1000, the rate during the same period being 19·7 in London and 18·4 in Edinburgh. The 190 deaths registered in Dublin during the week under notice showed an increase of 30 upon the number in the preceding week, and included 29 which were referred to the principal zymotic diseases, against 28 in each of the two preceding weeks; of these 21 resulted from diarrhœa, 9 from "fever," 4 from scarlet fever, 4 from whooping-cough, 1 from diphtheria, and not one either from small-pox or measles. These 39 deaths were equal to an annual rate of 5·8 per 1000, the zymotic death-rate during the same period being 2·1 in London and 3·0 in Edinburgh. The fatal cases of diarrhœa, which had declined in the four preceding weeks from 32 to 13, rose again to 21 last week. The deaths referred to different forms of "fever" which had been 4 and 6 in the two preceding weeks, further rose to 9 last week. The 4 fatal cases of scarlet fever also exceeded the numbers recorded in recent weeks, while the mortality from diphtheria and from whooping-cough showed a decline. The 190 deaths in Dublin last week included 48 of infants under one year of age and 34 of persons aged upwards of sixty years; the deaths of infants exceeded the number recorded in any recent week, while those of elderly persons showed a decline. Eight inquest cases and 10 deaths from violence were registered; and 58, or nearly a third, of the deaths occurred in public institutions. The causes of 12, or more than 6 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-MAJOR A. P. O'CONNOR has arrived in Dublin for duty. Surgeon-Captain C. W. Reilly has embarked on board the P. and O. s.s. *Canton*. Surgeon-Captain T. C. McCulloch has embarked for India. Surgeon-Lieutenants

Digitized by Google

J. Grech and J. A. Murison are warned to be ready to embark for India in the transport *Simla* at Southampton. Surgeon-Major R. H. S. Sawyer has embarked for Egypt.

The promotion to the rank of Brigade-Surgeon-Lieutenant-Colonel of Surgeon-Lieutenant-Colonel C. H. Swayne is antedated to July 24th, 1897, vice R. Harman, M.B., deceased. Surgeon-Captain William J. Smyth, M.D., resigns his commission.

NAVAL MEDICAL SERVICE.

The following appointments are announced: — Fleet-Surgeon C. C. Godding to the *Haulbowline*. Staff-Surgeons: William R. M. Young to the *Briton*, and Percy E. Maitland to the *Volage*. Surgeons: Ernest A. Shaw to the *Trafalgar*; Hugh P. Turnbull to the *Victory*; Walter B. Maurice, Walter H. O. Garde, Charles R. Sheward (for disposal), Eustace Arkwright, Edward D. J. O'Malley, and Walter R. Hopkins, all to the *Victory*; Frederick C. Stern and Henry Hunt, both to the *Pembroke*; Sidney Roach, Algernon C. Bean, and Robert H. Mornement, to the *Wildfire*; Moyle Breton, Richard F. Clark, Harold E. Fryer, Samuel Connor, and Edwin Folliott, all to the *Vivid*; Francis J. Barter to the *Heron*; Oswald Rees to the *Jackdaw*; and E. S. Reid to the *Seaflower*.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Robert Ebenezer Beveridge, M.B., 3rd Volunteer Battalion the Durham Light Infantry, to be Surgeon-Captain.

YEOMANRY CAVALRY.

Dorset (Queen's Own): George Herbert Staines Daniell, M.B., to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: 2nd East Riding of Yorkshire (Western Division, Royal Artillery): Surgeon-Major J. Sherburn, M.B., to be Surgeon-Lieutenant-Colonel. *Rifle:* 4th Volunteer Battalion the South Wales Borderers: Surgeon-Captain S. B. Mason to be Surgeon-Major. 2nd Volunteer Battalion the Royal Sussex Regiment: Brigade-Surgeon-Lieutenant-Colonel C. F. Lewis is retired under the provisions of paragraph 111 of the Volunteer Regulations, 1896, with permission to retain his rank and to continue to wear the uniform of the battalion on his retirement, vacating at the same time his appointment in the Sussex Volunteer Infantry Brigade. 1st Volunteer Battalion the Durham Light Infantry: The under-mentioned Surgeon-Captains to be Surgeon-Majors:—J. W. Blandford and G. Middlemiss.

THE ARMY MEDICAL STAFF.

There are various rumours afloat regarding the anticipated action of the authorities with the view of overcoming their difficulties in the way of getting candidates for the Army Medical Service. It is said that a new warrant is to be issued introducing a modified regimental system. A great many points have been conceded with the object of removing the grievances of which officers of the Army Medical Staff have complained, but nothing has been done to give effect to the recommendations of different committees and the strong desire of the medical officers themselves—viz., the formation of their service into a Royal corps, thus placing them on the same footing as the Royal Engineers and Royal Artillery. We do not understand why this should not be done, unless it be that the conferring of purely military titles upon medical officers has proved a stumbling-block in the way of the military officials.

We understand that the Quartermaster-General, the Director-General of the Army Medical Department, and the members of the Army Sanitary Committee visited the Portsdown Hills last week to select a site for a new military hospital for the troops in the Portsmouth garrison.

DRUGS ABOVE THE PROPER STRENGTH.—At a meeting of the Glamorganshire Local Government Committee held on Sept. 16th the report of the county analyst was presented. It stated that in one case a grocer had sold liquor nucis vomicæ eight times the usual strength; and in three instances spirit of camphor had been sold which was too strong, the excess being 8 per cent. in one case, 13 per cent. in another, and 16 per cent. in the third; 5 samples of tincture of benzoin were reported to be below the proper strength.

Correspondence.

"Audi alteram partem."

"THE ELECTION OF A DIRECT REPRESENTATIVE ON THE GENERAL MEDICAL COUNCIL."

To the Editors of THE LANCET.

SIRS,—On my return from Canada at the close of last week I was greeted with the unexpected news that Dr. Rentoul had resigned the chair in the General Medical Council to which he had been so recently elected by the voice of the profession. I found many letters urging me to re-consider my action in leaving the Council and to permit myself to be nominated for re-election, with assurances of earnest support if I would do so. I am profoundly grateful to my many friends for these proofs of confidence and appreciation; but, seeing that the causes which originally led to my resignation are all operative still, some with increased influence, I find it impossible to accede to the request.

But I am beyond measure pleased to see that my younger colleague, Sir Walter Foster, is again a candidate, and I most heartily wish him success. That his reappearance in the Council would be acceptable to that body is, I think, beyond question. His experience of its work and his parliamentary position alike point him out as a most eligible representative, and the profession is, in my opinion, to be congratulated on the opportunity afforded to it of again securing his services. Will the profession, for once, rise in its strength, and, putting aside the deadly apathy which has hitherto marred all the efforts of its representatives, unite to record its vote in favour of one who has already proved himself a worthy representative? Sir Walter is too well known to leave any room for doubt as to his capability, and his world-wide reputation marks him as a candidate whose claim cannot be surpassed.

I am, Sirs, your obedient servant,
C. G. WHEELHOUSE.

To the Editors of THE LANCET.

SIRS,—The impending election of a Direct Representative upon the General Medical Council is one of vital importance to the medical profession. It is so because the principle involved is that of reform. In Mr. Victor Horsley we have the undoubted champion of that cause. No other person knows more of the details connected with the questions of larger and those of lesser importance to the medical profession. No one is therefore more alive to the paramount necessity of reform. In casting their votes, then, it is to be hoped that the members of our profession will do so with the full knowledge that in voting against Mr. Horsley they are voting, not so much against him personally, but against the reform of the various anomalies connected with the constitution and government of the profession which exist at the present time. I am, Sirs, yours faithfully,

Hatfield, Herts, Sept. 28th, 1897. LOVELL DRAGE.

To the Editors of THE LANCET.

SIRS,—The profession must again appeal to your valuable assistance in the selection of a suitable candidate to fill the vacancy of Direct Representative on the General Medical Council. The latest development is remarkable. Sir Walter Foster is suddenly sprung upon the constituents, supported by a combination of strangely opposed elements. First he takes the place of the nominee of the Incorporated Medical Practitioners' Association, the council of which authority decreed that none but a general practitioner should have its support, nor any candidate who did not oppose uncompromisingly all legislation for the control of midwives. He is immediately taken in hand by the President of Council of the British Medical Association, and, lastly, has accepted the help of Dr. Rentoul. Surely the Council of the British Medical Association will have something to say to Dr. Saundby for assuming the responsibility of furthering the interests of any candidate without consulting the Association or his own Council. It may be argued that whatever official position a man may have, he has a perfect right to an individual opinion and to express it. Quite true, but there are some exceptional

Digitized by Google

circumstances in this connexion. At the annual meeting of the British Medical Association, when the conduct of the official organ was under consideration, there was a strong and almost unanimous feeling that the Association should take a foremost part in the selection of candidates as direct representatives on the General Medical Council, and that they should sit in that chamber supported by the influence of that large association, and the indifference of Dr. Saundby to the wishes of its members is wholly unjustifiable.

A committee was formed in Manchester immediately on hearing of the vacancy for the purpose of selecting a suitable, candidate and a telegram was sent by the officials to the Association, asking what action, if any, it was intending to take in the matter. This with a view to come to some general agreement as to the candidate to be selected. The reply was that they were "awaiting the instructions of the President of Council." This was on Sept. 14th. On the 16th a similar message was sent to Dr. Saundby's private address, and the reply received was that he was not expected home from Canada until the following Sunday. It is right, Sirs, that you should know this, and I sincerely trust you will unhesitatingly indicate in your Saturday's issue whom you deem to be the best candidate; and doubtless the profession will show its disapprobation of the conduct of the President of Council in its vote against Sir Walter Foster.

Accompanying Sir Walter Foster's address is a letter of recommendation of his fitness for the appointment, and it is signed by Robert Saundby, chairman, and C. G. Wheelhouse, and R. R. Rentoul, vice-chairmen. I will refer simply to two statements in this certificate of merit. These gentleman refer to Sir Walter Foster as a "tried and experienced medical reformer." A review of the minutes of the General Medical Council while he sat there will traverse this statement. Again, he is called a provincial practitioner! A word to the general practitioner. Sir Walter Foster backed one of the first Midwives Bills introduced into Parliament, and the worst Bill ever framed by the Midwives Institute and other unauthorised bodies. By this measure a poor man was not allowed to take proceedings against a midwife whatever injury she may have done to his wife during her confinement through either carelessness or ignorance, unless he first obtained the consent of the Attorney-General (see Clause 16). She was under no control and unless she thought fit was not required to send for a medical man, but was made the sole judge as to what was or what was not "natural labour." She had power to claim fees in court for operations. Is it likely any practitioner would lend his support to a candidate for a seat on our education board who had made proposals so dangerous to the public and so contrary to the honour, the dignity, and the welfare of our profession?

I am, Sirs, yours truly,

Old Trafford, Sept. 28th, 1897. JAMES BRASSEY BRIERLEY.

To the Editors of THE LANCET.

SIRS,—Everyone will admit that in Sir Walter Foster, M.P., and Professor Victor Horsley, F.R.S., we have two excellent candidates, and must regret to see them opposing each other. It is quite evident that nineteen-twentieths of their programme is identical and that the remaining one-twentieth is the midwives question. Essential as this difference is, I will not for the moment dwell upon it. Sir Walter Foster has faithfully served the profession for ten years on the General Medical Council, a mark of appreciation of which the British Medical Association recently presented him with its gold medal at the London meeting. For many years previously he had been identified with medical progress, having been qualified in 1860. On the other hand, Mr. Horsley has been President of the Medical Defence Union for four and a half years, and was qualified in 1881. There is thus a great difference between the experience of the two men in medical politics. There is evidently plenty of time before Mr. Horsley, without endeavouring to oust Sir Walter Foster just now; and as the former has had his four and a half years' experience in the Medical Defence Union, and the latter ten years on the General Medical Council, it will strike everyone as the wisest course for the benefit of the profession for each to go on with the work for which he is so eminently "fitted by his previous training" that Mr. Horsley so aptly quotes. We must also bear in mind that Mr. Horsley could not retain the above Presidency if he were elected on the General Medical Council. This would be a distinct loss to the profession and to the Medical Defence Union. I have no doubt that the strongest candidate to elect and the wisest course to take at the present juncture and best calculated to promote our interests is Sir Walter Foster, and thus enable Professor Horsley to continue as the President of the Medical Defence Union.

I am, Sirs, your faithfully,

G. H. BROADBENT.

Ardwick-green, Manchester, Sept. 28th, 1897.

To the Editors of THE LANCET.

SIRS,—Though other candidates may receive local support we may without offence assume that our choice for the vacant seat on the General Medical Council lies between Mr. Horsley and Sir Walter Foster. We are entitled, I think, to ask why Sir Walter Foster, who insisted last year on being relieved of the responsibilities of office, now seeks re-election, and why, having the reputation of a reformer, he comes forward backed by Sir Samuel Wilks, the reactionary members of the Council of the British Medical Association, and by Dr. Rentoul. The former represent the present spirit of *laissez faire* and *non possumus* (Sir Samuel Wilks even having publicly derided the notion that the general practitioner has any right to a reform of the grievances that press so heavily upon him), and the latter gentleman represents now—we scarcely know what.

Sir Walter Foster doubtless would describe himself politically as being a reformer, but as far as our profession goes it is difficult to see wherein his claim to be considered one lies. His position in the House of Commons, his place on the General Medical Council, and on the Council of the British Medical Association gave him large political power, and should have given him a wider political influence than any medical man has ever enjoyed, but nowhere and at no time has he ever originated any suggested professional reform, or himself formulated any such measure, either in the House of Commons or in the General Medical Council. The Medical Defence Union has received from him no support, but, on the contrary, direct hostility in the matters brought by them before the General Medical Council. A careful study of the Minutes of the Council will show, too, that Sir Walter Foster (with the exception of last year) hardly ever stayed long at any meeting—that he just put in an appearance and left, presumably for Westminster, where his presence was needed. It is a doubtful advantage to have a solitary Member of Parliament on the Council. His influence in the House is usually overrated, and any influence exerted by the General Medical Council at all is more effectually employed in the Privy Council Office and in the lobby of the House than in the House itself, while to divide the attentions of an official member between the House and the General Medical Council must inevitably result in the neglect of the work of the latter body.

If medical men wish for any reform in the legislation and grievances of our profession they must return a reformer and not a candidate who is put forward by the most reactionary influences. In Mr. Horsley we have a candidate sincerely interested in reform, of high scientific status, and, as he has proved by the position of the Defence Union, a capable man of affairs, honest and industrious.

I am, Sirs, yours faithfully,

Westerham, Sept. 27th, 1897. A. MAUDE.

To the Editors of THE LANCET.

SIRS,—The resignation of Mr. Jackson is quite as surprising as the resignation of Dr. Rentoul, and especially as he retires in favour of Sir Walter Foster. In order not to complicate the election I wrote to Mr. Jackson telling him that I would vote for him, and I would retire as I did not wish to have two general practitioners in the field. In a triangular fight Mr. Jackson would have had a good chance. Had I known that Mr. Jackson intended to retire I should certainly not have withdrawn. I should have liked to have seen this election tested on two points pure and simple: (1) the midwifery question, and (2) general practitioner *v.* consultant

Digitized by Google

as representatives. This would have simplified matters in future if decisively settled this time.

I am, Sirs, yours faithfully,

Halifax, Sept. 29th, 1897. TH. M. DOLAN, M.D.

To the Editors of THE LANCET.

SIRS,—I enclose a copy of a letter I have just written to Sir Walter Foster regarding what I call the unscrupulous and unfair tactics adopted by him or his committee, or both, in the conduct of the present contest for a general practitioner's representative on the General Medical Council, which I will thank you to publish in your next Saturday's issue. I will not comment on the fact that the lay press has been induced to scatter broadcast a false and misleading statement in order to buttress Sir Walter's position, which after the ten years' faithful services he so modestly alludes to surely ought to have been able to speak for themselves. In bare justice to myself I ask you to insert these two letters.

I am, Sirs, yours faithfully,

Winckley-square, Preston, Sept. 29th, 1897. JAMES A. RIGBY.

[COPY.]

15, Winckley-square, Preston, Sept. 29th, 1897.

Sir Walter Foster, M.D., Birmingham.

SIR,—I have just received a circular letter of your address enclosing a preliminary list of your alleged nominators and supporters. I notice with extreme regret that this list is headed with the following extract from the *Birmingham Daily Post*:—

"General Medical Council Election.—Mr. George Jackson, F.R.C.S., of Plymouth, who was the candidate of the Incorporated Medical Practitioners' Association, has retired in favour of Sir Walter Foster. Mr. Jackson's retirement means a great accession of strength to Sir Walter Foster, who is now practically the only provincial candidate."

I presume this letter and the enclosure were issued with your knowledge and sanction, and as the statement that you are "now practically the only provincial candidate" is both false and misleading I call upon you to withdraw it immediately in the same public and effective manner in which you have circulated it—that is by circular. You must be aware that I am as well as yourself a provincial candidate, nominated and accepted, and that my address was issued before your own. I remain, Sir, your obedient servant,

JAMES A. RIGBY, M.D.

To the Editors of THE LANCET.

SIRS,—It is with great pleasure that I see the address of Mr. Victor Horsley, announcing himself as a candidate at this election, and I trust that we shall seize this opportunity of securing for ourselves a real representative. Anyone familiar with the affairs of the last few years knows that there is not in the profession a man with a wider knowledge of the difficulties, or a broader sympathy with the trials, of the general practitioner than those Mr. Horsley has manifested. It is no exaggeration to say that our requirements and aspirations are as familiar to Mr. Horsley as they are to any of ourselves, and it is quite certain that he knows better than many of us how the improvement we desire can most hopefully be attempted.

If we consider what are the qualities most necessary to a representative who shall do us justice, we must perceive that it is in the first place requisite that the representative should have a full, accurate, and minute knowledge of our case and position. It is next desirable that he should honestly intend to apply his knowledge wholly and solely in our interest. Then it is needful that he should possess the intellectual qualities, the experience and knowledge of affairs which are essential to carry out his intentions and to give him due weight at the General Medical Council. Some of the correspondents who have expressed their views on this subject appear to look for qualifications other than these. Some seem to regard the kind of practice done by the candidate a matter more important than the kind of representation we are likely to obtain. What we want is a man to represent general practitioners, not a general practitioner to represent us. This should be obvious to everyone. The fact that a candidate has or has not any particular degree or diploma, or that he sees chiefly any particular branch of practice, is totally insignificant. We want a man, not a description, and we want him badly. Other correspondents seem to attach importance to geographical distinctions, though it is hard to imagine wherein lies the virtue or the disadvantage of any particular locality. Others have their vision so obscured by some special object as to be totally blinded to every other consideration. We have had representatives who have worked hard for us and others who have not done what their opportunities led us to expect of them. Now that we have got a splendid candidate who, as we well know already, will grudge us neither time, nor labour, nor brains, we can surely unite to secure a representative possessing in an eminent degree all the qualities that we require. If we cannot avail ourselves of our opportunity we are indeed unable to help ourselves, undeserving of the aid of others.

I am, Sirs, yours faithfully,

HAMILTON HALL L R.C.P. Lond., M.R.C.S. Eng.

Frant, Sussex, Sept. 28th, 1897.

To the Editors of THE LANCET.

SIRS,—I have, doubtless in common with the rest of the profession, received a copy of Sir Walter Foster's address as a candidate for the vacant seat on the General Medical Council. Sir Walter Foster's qualifications for the position are good, but in my eyes he is injured by those who prominently support him.

The question of the abuse existent in the out-patient departments of hospitals is a very acute one—one which concerns the general practitioner very deeply. It should certainly somehow—and soon—be brought within the range of the work of the General Medical Council. Is a candidate whose chairman of committee is Dr. Saundby likely to share this view? The corporations are decidedly over-represented on the Council. Is a candidate who is supported by the Presidents of the Royal College of Physicians of London and the Royal College of Surgeons of England certain to share *this* view? Lastly, a really good representative should know not only what are the real troubles of the profession, but what is the most practical way of relieving them. Will Dr. Rentoul's good word, which I observe Sir Walter Foster to possess, in any way guarantee to the profession that Sir Walter Foster is the owner of a definite policy?

I am, Sirs, yours faithfully,

Earl's-court, Sept. 29th, 1897. FRANK G. WALLACE, M.B.

*** We have received a great many letters on the importance of the impending election and the merits of the rival candidates for which we have been unable to find room. Some of the communications, moreover, lost their force by being signed only with a pseudonym.—ED. L.

"REFORM IN THE SPELLING OF THE MEDICAL VOCABULARY."

To the Editors of THE LANCET.

SIRS,—Which is best? To follow Dr. Gould's advice[1] in search of a "simpler spelling of medical terms" or to adhere to the old classical model? Who can follow or reconcile the barbarous discordances of English "as she is spoke" by cockneys, provincials, Americans, and other slaves of accidental training? It is more difficult to trace and understand these than it is to appeal to the classical standard of Greek etymology. Etymology speaks to all nations alike. It is the only constant and intelligible authority. In the evolution of science the need for a new word to express a new idea is continually arising. The scientist naturally turns to the Greek Lexicon for what he wants. Here the classical student finds at once a fair expression intelligible to those whom he addresses, no matter what their mother tongue may be. Greek is the mother tongue, indeed, the grandmother tongue, of the scientific student of every land. It is the common tongue which binds them together in the fraternity of knowledge.

If it be urged, as those who accept the cacophonic rule of Dr. Gould must do, that words adopted in the English language must be trimmed in accordance with the accidental current habits of pronunciation we are landed in endless confusion. As pronunciation changes spelling must change, and so the meaning of the word is an ever-shifting enigma. If it be urged that it is easier to understand English than Greek the obvious answer is that Greek is a fundamental factor in medical education. Hence scientific words drawn from the Greek convey at once a definite meaning. And there is the obvious danger of losing this meaning if we alter the spelling in senseless deference to the disciples of cacophony. Etymology speaks to all alike. It is the only constant, intelligent, and trustworthy guide.

I am, Sirs, yours faithfully,

Lyss, Sept. 27th, 1897. ROBERT BARNES.

To the Editors of THE LANCET.

SIRS,—In the interesting leading article in THE LANCET of Sept. 25th on "Reform in the Spelling of the Medical Vocabulary" the writer is guilty of one slip. He says: "'Empyema' is now never written 'empyæma.'" It never

[1] THE LANCET, Sept. 18th, 1897.

Digitized by Google

was so written. More than 400 years before Christ Hippocrates repeatedly wrote *ἐμπύημα, a gathering or suppuration*,[1] or *an abscess*, especially *an internal abscess*.[2] Nay, more, the Father of Medicine gives us the derivation of *ἐμπύημα*, for in "Prognostics," page 43, he uses the verb *ἐμπυέω*, which means *to have abscesses in the lungs*. This verb is, of course, in its turn derived from *πύον*, *discharge from a sore matter* (Latin *pus*).[3]

This very word empyema may serve to illustrate my opposition to Dr. George M. Gould's proposed reformation of English spelling. If his suggestions are adopted it will be next to impossible to trace the history of words and to recognise their hidden meaning. Changes in spelling have, of course, taken place in the past—one has only to read Trench's "English Past and Present" to become aware of this—nay, more, changes are taking place and will in the future take place. But this is being effected by what the writer in THE LANCET aptly calls "the ordinary evolution of language," when "the unconscious impulse of the English-speaking race tends in that direction."

I am, Sirs, yours faithfully,
JOHN WM. MOORE, M.D. Dub.,
Ex-Scholar, Trinity College, Dublin.

Fitzwilliam-square West, Dublin, Sept. 25th, 1897.

"AN IMPROVED ŒSOPHAGEAL PROBANG."

To the Editors of THE LANCET.

SIRS,—Looking over back numbers of THE LANCET I find an illustration in the issue of Sept. 18th of "an improved œsophageal probang," by Mr. C. J. Mayhew, and a letter from Dr. Sympson in THE LANCET of Sept. 25th claiming priority on the ground of publication of a similar instrument in January of the present year. But the second edition of my book, "The Throat and its Diseases," published so far back as June, 1887, contains an illustration, Fig. 101, page 142, of an instrument constructed to overcome both the difficulties it has occurred to these gentlemen to correct—viz., that of premature expansion of the ramoneur on insertion and the employment of but one hand; and both—as I venture to think—by a better mechanism. Moreover, my instrument is made in jointed form, so as to occupy less space in the pocket or instrument case, while the end, instead of being of sponge, is replaced by an aseptic metal point, which has the additional advantage of detecting any hard foreign body on percussion.

I am, Sirs, yours faithfully,
Mansfield-street, W., Sept. 27th, 1897. LENNOX BROWNE.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Sept. 25th a correspondent asks leave "in fairness" to remind you that you published a notice of an œsophageal probang designed by him, which, he says, embodied the improvements claimed for mine. Does your correspondent consider it unfair of you to publish a notice of a probang which is entirely different, and which I consider simpler, in construction to his? I am unable to understand how the probang illustrated in THE LANCET of Jan. 9th this year is more easily opened and withdrawn with one hand than the old form of instrument.

Messrs. Mayer and Meltzer have informed me that some years ago they made for Mr. Lennox Browne a probang with catch which prevented opening during insertion, but it required the use of both hands to manipulate it.

I am, Sirs, yours faithfully,
King's College Hospital, London. C. J. MAYHEW.

*** Each inventor has aimed at obviating the same difficulty, but the mechanisms employed are entirely different.—ED. L.

THE BATTLE OF THE CLUBS: THE COVENTRY PROVIDENT DISPENSARY.

To the Editors of THE LANCET.

SIRS,—As secretary of the Coventry public medical service I have been requested to forward you a copy of a letter, dated Sept. 5th, 1897, to the medical staff of the Coventry Provident Dispensary, also a copy of the *Coventry Herald* for Sept. 4th, 1897. My committee feel that the reply of the Coventry Dispensary committee to the memorial of their medical staff was insulting, not only to that staff, but to the whole profession of medicine. In intimating to its medical staff "that if they were not satisfied with their position the dispensary would be quite prepared to get a medical staff exclusively for the institution," the committee were taking a low estimate of professional men in the town and elsewhere, and considering that the Coventry public medical service is open to the dispensary staff upon their resignation, and that ultimately their financial position will not be impaired, there seems to be no reason why they should not stand to the terms of their memorial. With a view of assisting them in such a course the following letter was addressed to them on Sept. 5th, and on the 25th last the enclosed reply was received.

I am, Sirs, yours faithfully,
EDWARD PHILLIPS.

Much Park-street, Coventry, Sept. 28th, 1897.

[COPY.]

20, Much Park-street, Coventry, Sept. 5th, 1897.

TO THE CHAIRMAN OF THE COVENTRY DISPENSARY MEDICAL STAFF.

DEAR SIR,—As secretary of the Public Medical Service I have been instructed to write to you to express the regret of my committee that you have failed in your efforts with the dispensary committee to carry out any of the reforms asked for in your memorial to them. If the report in the *Coventry Herald* of Sept. 3rd be a correct one my committee much regret that any body of professional men should be exposed to such an insult as the following paragraph would imply: "The present arrangement with regard to salaries the committee consider fair both in the interests of the patients and the medical staff, and they are not disposed to disturb it. The general feeling of the committee on the whole question is that if the medical staff are not satisfied with their position the dispensary would be quite prepared to get a medical staff exclusively for the institution, as is being done in some other towns, notably at Yarmouth."

Taking into consideration the verdicts already pronounced on your dispensary system by THE LANCET, the *British Medical Journal*, and the Ethical Committee of the British Medical Association, we are of opinion that there is nothing open to you but the resignation of your appointments. Supposing such a view were accepted by yourselves, and you were at once willing to resign your positions as members of the staff, it is our intention to cordially ask you to join the public medical service, and become members of a professional body which is able to control all contract work undertaken by its members.

We are anxious to assist you by this offer in resenting an insult which has been offered through you to the whole profession of medicine.

I am, dear Sir, yours faithfully,
(Signed) EDWARD PHILLIPS.

[COPY.]

24, Bishop-street, Coventry, Sept. 25th, 1897.

DEAR SIR,—I beg to acknowledge the receipt of your letter of Sept. 6th. As negotiations are still pending between the staff and the committee of the dispensary I am instructed to say that we are unable to adopt your suggestions.

I am, dear Sir, yours faithfully,
(Signed) W. J. PICKUP,
Sec. Medical Staff of Coventry Provident Dispensary.

To Dr. Phillips.

"CONGENITAL ABSENCE OR DELAYED DEVELOPMENT OF THE PATELLA."

To the Editors of THE LANCET.

SIRS,—In connexion with Mr. Little's original article on Congenital Absence or Delayed Development of the Patella, published in THE LANCET of Sept. 25th, the following case, at present in the wards of the Manchester Children's Hospital, under the care of Mr. Wright, may possibly be of interest as illustrating the usual association of the above condition with other extensive congenital deformities. A girl, aged six years, was admitted to hospital on Aug. 7th; she was rather a delicate-looking child and of small build for her age. Both knees were in a position of hyper-extension of about 20°; both admitted of very slight flexion only—the right until the leg and thigh were in a straight line, the left to a further extent of 10°. The left also permitted a slight degree of lateral movement. The left joint line was perfectly horizontal, but owing to the abnormally large size of the inner condyle of the right femur the right joint line was somewhat oblique from within upwards and outwards, causing a slight appearance of genu valgum. On the right side no trace whatever of any patella could be found, and on the left all that apparently represented it was a fibro-cartilaginous nodule about the size of a pea situated in the quadriceps tendon one inch above the joint line. There was also very marked congenital dislocation of both hips, the femora being abnormally moveable on the pelvis, it

Digitized by Google

being possible to push the rudimentary femoral head to within half an inch of the anterior superior iliac spine. The right foot was in a position of marked talipes equino-varus, the left in that of severe calcaneo-valgus.

All these deformities were congenital, and yet in spite of their extent the child could walk about without assistance and had done so ever since the age of two years. The body-weight was transmitted to the ground through the outer border of the cuboid and anterior part of the os calcis in the right foot and the projecting head of the astragalus on the inner side of the left foot. The knees were held perfectly stiff, and the pelvis sank on the femora at each step, the characteristic waddle of congenital dislocation of the hip being extremely well marked; the abdomen was held prominently forward, and the shoulders thrown well back. On Aug. 17th the deformity of the feet was corrected by operation, Mr. Wright performing double astragalectomy. While the patient was under the anæsthetic forcible attempts were made to further flex the knees, but without avail.

I am, Sirs, yours faithfully,

ARTHUR H. BURGESS, M.Sc., M.B. Vict., M.R.C.S. Eng.,
House Surgeon, Manchester Children's Hospital, Pendlebury.
Sept. 27th, 1897.

INFECTION AND THE NOTIFICATION ACT.

To the Editors of THE LANCET.

SIRS,—Your annotation on "Infection and Parental Responsibility" in THE LANCET of Sept. 11th induces me to make a few remarks on a subject I have frequently ventilated and which has direct bearing on the above. Why do parents ignore the responsibility the above Act places on them? From many years' experience I have no hesitation in saying that it is not from ignorance, carelessness, or from a desire in all cases to even avoid the medical man's bill that they do not call in medical aid; but it is to avoid the loss of the wage-earning factors of the home that accompanies the consequence of notification.

The avoidance of the medical man's bill in mild cases is undoubtedly an inducement, but not in all, since a large number of juveniles of the artisan and other classes belong to clubs, and there would be no reason for not claiming the services of the medical officer which they were entitled to, particularly when in my experience a child aged six years drew 6*s*. a week when under the medical officer's care. The fact is that in most families of this class the elder children bring in several shillings a week by doing odd jobs out of school hours—boot-cleaning, butcher's errand boys; and, in fact, in many cases are employed to take out the medical officer's medicines. The mother, too, goes charing or takes in washing, and all these sources of income are cut off the moment the medical officer appears and notifies. Further, the husband, perhaps a baker or a milkman, must either give up work or leave his house for some weeks in cases of some diseases. If these restrictions were not enforced the Act would be useless. I confess I have ever found parents willing to carry out advice and instructions, but they have clearly stated the grievance they considered they had. And I must say, on looking over a record of some years, I find that since the Act was adopted in the majority of scarlet fever cases I was only called in to the more serious at the commencement, and in most when some sequelæ of the disease were manifest, the usual being nephritis and dropsy. Then all came out, with such remarks as, "Yes, the child did complain of sore-throat, was sick, and the neighbour's children are ill, but I never saw any rash, and did not think it could be scarlet fever. I have seen no peeling," &c. In some cases even when pointing out that the latter symptom was present in addition to the nephritis which had alarmed them they would not believe the child had the fever. I believe this experience will be found to be not uncommon. But I have constantly, realising the hardship to the poor in such cases, asked if it could not be remedied.

Section 9 of the Notification Act says: "Any expense incurred by a local authority in the execution of this Act shall be paid as part of the expenses of such authority in the execution of the Acts relating to Public Health, and in the case of rural authorities shall be general expenses." The Infectious Diseases (Prevention) Act, Section 20, provides for any expense incurred, including reasonable remuneration of any veterinary surgeon employed under Section 4, and as "part of the expenses of such authority," &c. (same as above), and Section 6 provides for the free disinfection of bedding, &c., at the expense of the authorities, as also for *compensation* to the *owner* when *damage* (loss) is sustained.

Now, Sirs, why should not the poor be compensated for in many cases the serious loss they suffer in carrying out the necessary isolation of the whole family? I feel sure that the only way to reap the full benefit of these Acts is to do so, and I have no hesitation in saying that if it were done parents would be as willing to help medical men, instead of as now thwarting them, in stamping out these infectious diseases as we are ourselves. Moreover, penalties for infringement of the Act could be rigidly inflicted, as all sentimental grounds for leniency would be removed by knowing that the parent suffered no loss from carrying out the Act. Under the head of "general expenses" and "as part of the expenses of such authority in the execution of the Acts relating to public health" I submit that local authorities have the requisite power to make good the few shillings' loss sustained by the enforced idleness of the mother and healthy children. "The execution of the Acts" surely means the *efficient* execution, and if, as I assert, the efficient working of the Act can only be obtained by removing all cause for concealing facts on the part of the public by making good the loss, it is a rightful and legal charge as the "general expenses."

I am, Sirs, yours faithfully,

ELLIOT DAUNT, M.R.C.S. Eng., L.R.C.P. Lond., D.P.H.
Sept. 20th, 1897.

"IMMORALITY AMONG SCHOOL BOYS."

To the Editors of THE LANCET.

SIRS,—Dr. Hime's article in THE LANCET of Sept. 4th is necessarily helpful. The question of immorality amongst boys is one which requires bold yet careful handling. It is a matter, as he points out, that must be attacked alike by the medical man, the parent, and the schoolmaster. Dr. Hime, I take it, is thinking simply of masturbation. Everything that he advocates for the suppression of the evil is excellent, nothing, perhaps, that he says being of such importance as the insistance of all boys entering thoroughly into the school games and sports. He says nothing about diet. The principal meals should be breakfast and midday dinner. Eggs and so forth may also be allowed for tea, but supper should be quite a light meal, a glass of milk or cocoa with bread and butter or biscuits being quite sufficient. No healthy boy requires alcohol, but when it is allowed it should be consumed only at the midday meal. Masturbation is looked upon as "a solitary vice." It is not always so; the worst examples of it are those where boys openly masturbate themselves before their fellows, or even stimulate the passions of others by, so to speak, masturbating their comrades. Undoubtedly these are the boys that do the greatest amount of harm, and who deserve the severest form of punishment for their misdeeds. Perhaps I am trespassing too much upon the schoolmaster's domain when I suggest that even these boys should not be expelled offhand. They would undoubtedly deserve a sound thrashing, and the reasons for which they have been punished should be known throughout the school. Any head-master would, I am sure, follow the punishment with kind but severely applied advice.

I have had, of course, to talk to boys upon this subject, and I never fail to try to impress them with the "beastliness" of the habit. I tell them that we kick a dog if we catch him doing the same thing—kick him and call him a dirty brute. Solitary masturbation needs a more kindly way of treatment. Here, at least, the boy has some conscience; he is ashamed of what he is doing and does it on the sly, and very frequently is quite unaware of the harm that he is doing to himself. That this particular form of the vice requires kind as well as firm treatment is evidenced by such facts as these—that I have spoken with schoolmasters and athletes of large repute, who have owned to me that in their younger days they had yielded to the temptation. Warned in time, however, they gave up the habit. It should ever be borne in mind when dealing out punishment for this offence that, after all, the offenders are only gratifying one of the strongest impulses of nature at an age when natural desire powerfully asserts itself. Boys, we must also remember, are not the only offenders; girls, men, and women are by no means always saints in this respect. Yet, remembering all this, and weighing well the strength of passion and the weakness of poor humanity, the offence has to be controlled, nay, has to be prevented. *A repetition* of open beastliness after due punishment and warning can only be further dealt with

Digitized by Google

in the case of the schoolboy by immediate expulsion. The medical man should make a most careful local examination in every case—I mean that he should carefully examine for any local cause that might be a predisposing reason for the commencement of the habit. Many local causes of irritation at once suggest themselves.

In my opinion, a carefully written pamphlet should be put into the hands of every public school boy. The bad moral effects of the habit, and its absolutely "beastly" nature, should be carefully pointed out. Such an attempt has already been made, but I think the statement of the facts should be even more plainly put down, and how to avoid temptation should be set forth with no mincing words. The great objection brought forward to such a scheme is that by its means every boy will be told of the existence of the evil when he might have altogether missed such pernicious knowledge. That is nonsense; every boy will know something about it sooner or later, and to be forewarned is to be armed for resistance. I am drawing up the draft of such a pamphlet, and shall submit it to the criticism of both headmasters and medical men, and if I am sufficiently supported shall publish it for the purpose of being distributed in the public schools.—I am, Sirs, your obedient servant,

"THE MEDICAL OFFICER TO A PUBLIC SCHOOL."

Sept. 20th.

THE COMPARATIVELY STATIONARY DEATH-RATE IN PRIVATE OBSTETRIC PRACTICE.

To the Editors of THE LANCET.

SIRS,—I have been much amused by an incident which has just occurred to me in the ordinary run of practice, but I venture to think that the amusement is so blended with instruction that it is not impossible that you may consider an account of it worthy of a place in the columns of THE LANCET. There could be no more forcible example of the ignorant empiricism which obtains even in the metropolis of the world, and of the fatally irreparable consequences which necessarily follow upon medical practice which is subservient to it. Some time ago I enjoyed the pleasure and privilege of a prolonged residence in the Rotunda Hospital, the practice of which I do not hesitate to say constitutes both the most carefully carried out example and the most brilliant result of the principles of asepsis which has yet been shown anywhere. Upon taking up my residence there, whilst admiring the training involved in the perfect attention to details, my mental attitude towards the practical good gained was inclined to a little benevolent scepticism. However, the practical results constantly brought under one's notice during the brilliant mastership of Dr. Smyly, and which now continue under Dr. Purefoy, were, and are, so striking as to convert the most unbelieving; and I never knew anyone during my term of residence there who did not enthusiastically admit this. Those who have been in actual practice since the pre-asepsis period, and who are conversant only with the well-known fact that the rate of mortality in private obstetric practice has not decreased in anything like the same ratio as that of the great maternity hospitals, cannot do better than consult the table given in Dr. Jellett's "Short Practice of Midwifery" of the cases treated at the Rotunda Hospital during the seven years of Dr. Smyly's mastership, which in the last year reached the astonishing minimum of 0·06 per cent. In producing this result few things were more important than the precautions taken in making, and the reduction in the number allowed of, vaginal examinations; and by way of impressing this in his clinical teaching Dr. Smyly had a well-known saying that "he hoped to live to see the day when a vaginal examination would be looked upon in much the same light as turning—a serious operation in midwifery." One does not require much experience of the exigencies of general practice before recognising that literally this is impracticable in every-day work; but for my own part I try to keep it before me as the (unattainable) ideal. Last month I attended a primipara who had a moderately long, but in every way satisfactory, labour. She had as "acting nurse" an individual who seemed to be a kind of general charwoman, and whose previous attendances at labour cases had been, according to her own account, very limited indeed, and whose general demeanour corroborated this. I was called to the case in the middle of the day, but there was then no sign of dilatation of the os. I called again during the early part of the afternoon, but found no progress. About six o'clock in the evening I received an urgent message from the "nurse" to say that the expected event was coming off immediately, and the terms of the message were so imperative that I rose from my half-finished dinner and went immediately through a heavy shower of rain. Upon my arrival I found the patient in practically the same state as when I had last seen her and labour not a bit further advanced, but in order to satisfy her I stayed for about an hour. I then went to fulfil some other engagements, and got back to see her again about eleven o'clock, at which time I found matters at a standstill. I again stayed for about a couple of hours, but seeing that it was the usual prolonged first stage of a primipara I administered two drachms of syrup of chloral and went home to get some sleep, leaving instructions with the "nurse" that I was to be sent for if required. I did not receive any message, so I went to see her again after breakfast and found her in much the same state as on the previous evening. I called again about two o'clock with the same result. Finally, I was sent for about four o'clock, and finding that at last labour was progressing I remained with the patient in the usual way and the infant was born about half-past six in the evening. Everything terminated satisfactorily, and I thought no more about the case after the end of the usual period of visiting, and the patient and her friends were apparently very well satisfied. Yesterday, however, I called to see a medical friend who practises in the same neighbourhood, and he told me the story which is the gist of this communication. He said that a week or two ago he was attending a confinement when the same individual was again acting as nurse in the same *dilettante* kind of way to another friend of her own. This Betsy Prig inveighed mightily against me, and her two weighty reasons for asserting that I "knew nothing about midwifery, and probably had never seen a case before," were (1) that I was too particular and over fastidious about scrubbing and washing my hands before making an examination; and (2) that I did not make a sufficient number of examinations and "help" the patient (oh! shade of Dr. Smyly! I made at least two vaginal examinations *during each visit* which I have related).

My friend tells me that this good woman is emphatic in her declamations that never again shall I be permitted to attend any woman she can influence. Circumstances, however, make this threat of hers quite inoperative, but if I had been permanently in the neighbourhood it might have been quite a serious matter for my reputation to have this criticism of incompetence spread about. As it is, I think it is worth while recording as an example of the never-ceasing risks attending the conscientious practice of the profession. Few things are from their nature more pathetic than death in child-bed, and anyone who has ever seen such devoutly hopes he may never see another, and with this object will spare no pains to diminish the inevitable risk. Still, if a man stands to lose his reputation because by scrubbing his hands he seems fastidious about being brought into contact with the patient, or by reason of abstaining from unnecessary vaginal examinations he is accused of not sufficiently "helping" the patient, what course can he be expected to adopt? With so-called "nurses," and by more than parity of reasoning their patients on such friendly terms with the streptococci, can the notorious fact to which I have referred, the comparatively unaltered death-rate in private obstetric practice, be at all a matter of surprise? In fact, it is inevitable.

I am, Sirs, yours faithfully,

London, Sept. 22nd, 1897. M.D.

THE GUILD OF ST. LUKE.—The Medical Service held last year at St. Paul's Cathedral under the auspices of the Guild of St. Luke was so much appreciated that it has been decided to hold a similar one this year on Oct. 19th at 7.30 P.M., when the Archbishop of York will preach the sermon. On account of the large attendance last year it has been found necessary to limit the number of tickets. Invitations will be issued to all practitioners of medicine resident in London and those who are graduates are asked to wear academical costume—that is to say, the gown and hood of their degree, whether medical or otherwise. Practitioners residing in the provinces who wish to attend can obtain tickets on application to either of the honorary secretaries, Dr. S. Russell Wells, 24, Somerset-street, Portman-square, W., or Mr. C. Devereux Marshall, 10, Devonshire-street, Portland-place, W.

THE EPIDEMIC OF TYPHOID FEVER AT MAIDSTONE.

(BY OUR SPECIAL SANITARY COMMISSIONER.)

THE serious and startling character of the typhoid fever epidemic at Maidstone involves so many issues and problems that it is yet too early to express a definite opinion or formulate accusations. One thing only can be said with the conviction that future investigations will not disprove the assertion. The water-supply has undoubtedly been the spark which has ignited the powder. It would, however, be imprudent at this early stage to conclude that the water-supply constitutes at once both the spark and the powder which has produced the explosion. Considering that in this small town, with only some 33,000 inhabitants, there have already been more than 900 cases, it seems certain that other causes besides the water-supply must have contributed to bring about this dire result. Under the present circumstances it will be fortunate, indeed, if ultimately the number of cases does not exceed 1000 and reach 3 per cent. of the population. With such figures before us it is difficult to believe that the water is alone to blame. There must have been predisposing causes of a very active character, and therefore it is only right to insist, and this at once, that other reforms besides an improved water-supply are needed. Nor is it necessary for the moment to say much in support of this opinion: it will suffice to observe that in Maidstone many closets, though draining into sewers, have no flushing apparatus, but depend for their cleanliness solely on the water that may be brought to them in buckets by the inhabitants. What this is likely to mean in actual practice anyone with a little experience in such matters will fully appreciate. Having said this much and made these reservations with a view to future criticisms and elaboration of details we must for the moment content ourselves with giving a short history of the epidemic and some account of the much-abused water-supply.

THE HISTORY AND PROGRESS OF THE EPIDEMIC.

During the course of the month of August the medical officer of health, Mr. Adams, became aware that there was an unusual prevalence of diarrhœa in the borough. Though an increase of this disease is to be expected at that time of the year, he was startled on preparing his monthly report to find that during the four weeks ending Sept. 4th there had been 19 deaths from diarrhœa. The local board meeting was to take place on Sept. 15th, and on the 12th six cases of typhoid fever were notified to the medical officer of health. Another case was notified on the 13th, three on the 14th, and one more on the 15th, when the board met. The medical officer at once drew up a handbill setting forth the precautions that were to be taken to prevent diarrhœa and enteric fever, urging the necessity of boiling the milk, drinking water, &c., of reporting any case of faulty drainage, and of abating all nuisances. With commendable promptitude these instructions were printed and circulated broadcast within a few hours of their approval by the board. In the interval the medical officer of health had naturally suspected the milk-supply and had undertaken an investigation on the subject. This was no easy matter, for though the general sources from which the milk-supply is derived were known, still they varied in detail. Many purveyors obtain their milk from large dairies, and the milk does not always come from exactly the same place, so that it took some time to unravel this matter. The medical officer did not yet suspect the water-supply, but he feared that it might become contaminated in consequence of the number of cases of typhoid fever in the neighbourhood. It was therefore more for the purpose of protecting than of denouncing the water that he went up immediately to London to submit samples to Dr. Washbourn for bacteriological examination. But when, on Sept. 16th, no less than 27 new cases of typhoid fever were notified he began to suspect that the water was the real cause. By the 16th there had been in all 38 cases of typhoid fever in the borough. This number was already sufficient to begin to localise the disease and to observe that certain quarters of the town were more affected than others. But as on the morrow, Sept. 17th, 26 other cases were notified, and on the 18th 66 more cases were reported, not only was the gravity of the epidemic self-evident, but the map on which these cases were dotted down clearly showed that the epidemic was connected with what is known as the Farleigh water-supply and not with the other sources of supply. This was all the more evident as the Farleigh water is delivered, not to one district, but to three districts which are widely separated from each other. It was in the north-east, in the south-east, and the western quarters of the town that the epidemic prevailed. A case in the central quarter of the town which separates these districts one from the other only served to confirm this theory. The case was that of a servant who was employed in King-street—a thoroughfare which is situated in the central district. Though she had typhoid fever no other inhabitant of the house in King-street suffered from that disease. But it was ascertained that this servant had previously been home to her parents from Saturday to Sunday, where she had drunk some water. Her parents live in Gladstone-road, which is situated in the north-easterly district, and which receives the Farleigh water-supply. By Sept. 18th the evidence was sufficiently emphatic to enable the medical officer of health to approach the water company and insist on a full investigation. This was commenced on 19th, and on that day no less than 76 more cases of typhoid fever were notified, while on the next day, the 20th, there was a further and most alarming increase of 129 new cases. Such figures show only too well the utter impossibility of attempting to overtake the evil when once it has been allowed to occur. In such cases prevention is the only safeguard.

BAD WATER: THE TUTSHAMS AND THE HOPPERS.

The Farleigh water-supply is collected from three separate gathering grounds and springs. The farthest of these gathering grounds is near Ewell House and some four and a half miles from Maidstone. Nothing has yet been ascertained concerning this supply beyond the all-important fact that a junction is effected between the pipe that brings the water from the Ewell district and that which brings the water from the second or Tutsham gathering grounds. This latter ground is divided into two districts, Tutsham-in-Fields and Tutsham-in-Orchard. In the former district the water is collected by means of draining-pipes which are sunk in the subsoil. This soil is composed of the rag or lower greensand formation. The pipes were laid some thirty years ago, and who shall say how or where? Some are supposed to be twenty feet down in the soil, others are known to be only seven feet below the surface, and perhaps some pipes are still nearer to the surface. Apertures are, of course, contrived so that the pipes shall receive and convey away the water that is in the soil above them, and this earth is planted with hops. Of course the hops have to be manured, and much has been said concerning the obnoxious character of this manure. Fish, rape dust from oil mills, and shoddy are employed. But all this is placed on the soil in the month of January, and if the manure had been the cause the epidemic should have broken out earlier. When we examine the position of the collecting tank into which the water from these pipes is delivered we find a more likely explanation. This tank or catch-pit is covered over with two large slabs of Yorkshire flagstone and a little earth. This is not a sufficient impediment to prevent a direct percolation into the tank. There is but a small yield of water in this tank and it is very turbid. But the situation of the tank itself is far more suggestive. It is close to a long hedge. On either side of the tank there is a vacant space which is utilised as a camping ground. Here gipsy vans and other vans are stationed at certain periods of the year. On the other side of the hedge there was a great accumulation of fæcal matter, this being a convenient retreat for the hop-pickers and others who work in the neighbourhood. From the collecting tank which is so dangerously close to this foul hedge a pipe conveys the water in front of a row of eight cottages that are close at hand. These are known as the Mill Cottages. They derive their water-supply from this pipe. It is brought behind the cottages by a branch pipe and there affixed to a pump. The inhabitants of the Mill Cottages are therefore not only the first to drink the water from the Tutsham gathering tanks, but they drink this water undiluted by mixture with water from other gathering grounds. The medical officer of health therefore made a careful inquiry as to the health of all the inhabitants of these cottages. The inhabitant of the first cottage keeps a small huckster's

Digitized by Google

shop, and she declared that the whole of her family and herself had been very ill with diarrhœa; but, what was more remarkable, it appeared that the hop- and fruit-pickers who worked in the neighbourhood had also suffered extensively, for they constantly came to her shop to buy a diarrhœa mixture. Further, this woman had heard that a child had died from fever and diarrhœa in one of the hop-picker's huts. In the next cottage the whole family had suffered more or less from diarrhœa, and confirmed the story of the death of the child. At the third cottage both mother and son suffered from attacks of diarrhœa about three weeks or a month previous to Sept. 19th, when the epidemic at Maidstone had assumed such serious proportions. In the next cottage a man had been on his club and suffered from diarrhœa in the months of July and August. In another cottage a woman remarked that the hop-pickers came on Aug. 20th, and her baby was very ill on the 24th. In two other cottages the inhabitants had also been very ill with diarrhœa, and the baby belonging to a friend who had paid them a visit suffered in the same manner.

A second gathering tank or catch-pit at Tutsham is known as Tutsham-in-Orchard. It has an overflow pipe which feeds a watercress bed. On the other side there is a blacksmith's shop where there is a privy, which might also be the cause of mischief, and there is the general consideration that the whole district is overrun with hop- and fruit-pickers.

THE FARLEIGH MAIN.—THE DISUSED FILTER-BEDS.

Thus we have seen that the Farleigh water-supply is derived first from the catch-pits in the Ewell district. The pipe from this district is joined just below the mill cottages by a pipe from the Tutsham-in-Fields and Tutsham-in-Orchard district. The pipe, or main as it may be called, now approaches the River Medway and passes underneath it by means of a syphon. It then runs along the side of the South-Eastern Railway line; and on the other side of this line there is another gathering ground known as the Barming sources. The water is here derived from ragstone beds at their juncture with the Atherfield clay. The catch-pits are placed on a parallel with the railway line on the north side between the railway embankment and a hedge. The gathering grounds are beyond the hedge and are covered with orchards. The water is brought to the catch-pits by iron pipes, loosely jointed so that the water may enter between the joints. The catch-pits are made of concrete and bricks set in cement. The manholes are well protected with cement and keyed down. That such precaution is necessary is shown by the fact that a few years ago platelayers and other labourers employed on the railway line used to unlock and lift up the covers so as to take water out of the catch-pits. The pipes that gather the water have not been touched for something like thirty years, but as they are situated at least a quarter of a mile from any houses or barns they can only be contaminated by the manure in the orchards or by the fruit-pickers and others who work on the spot. Then it has still to be shown whether such contamination would not be nitrified before it reached the level of the pipes. From the catch-pits iron pipes pass under the railway line at a depth of about seven feet and join the delivery main which has brought from the other side of the river the waters from the Ewell and Tutsham districts. This main, which has now united and so mixed together the three sources of supply, continues between the railway line and the river till the Farleigh station collecting tanks are reached. There is no evidence as yet that the last of the three gathering fields has yielded polluted water. The eastern catch-pits do not receive much water. In the opposite direction those known as the Church springs have a good yield; they are supplied by pipes that have been laid more recently, about fifteen years ago. They are considered more satisfactory, and the water comes from a steep bank of ragstone. But some of the catch-pits near the railway line and the orchards have a few cracks in the cement and might be polluted by water soiled with excremental matter due to the occasional presence of fruit-pickers. This is not considered probable, but it is possible. On the other hand, it is not thought possible that the Medway, even at flood-tide, could have any effect on the water. However this may be, the water, as already described, is mixed in the main with that which comes from Tutsham-in-Fields, and there can be but little doubt as to the pollution of the latter.

Close to the large collecting tanks, where the water from the three gathering grounds is brought by the delivery main, there are two filter-beds, consisting of two feet of sand and one of pea gravel. These filter-beds should have saved the town, but it appears that they were not in use. One of the filter-beds is of recent structure and the other is dry. When they were used they were frequently cleaned, but the cleansing has nothing to do with the present epidemic, for of late the filters have not been used at all. It was thought that the pipes connecting the filter-beds and the pumping station were liable to pollution from the river, and the culvert was supposed to be in an unsafe condition. Therefore the water was brought from the collecting tanks by a pipe placed outside the filtering beds straight to the pumping stations. From here the water is pumped along a rising main to what is known as the Barming Reservoir. From this point the water can be supplied by gravitation to the greater part of the town. When the Barming Reservoir is full a valve is shut and the water by another pipe reaches the Asylum Reservoir, which is situated at a still greater altitude and supplies the highest parts of the town. The reservoirs were cleaned out fifteen months ago. The delivery service is under pressure and through a 12-in. iron main. From these two reservoirs the north-east, the south-east, and western districts of the town have been daily provided with unfiltered water composed in part of the water gathered at Tutsham-in-Fields, which some three to four weeks before the outbreak of the epidemic caused all the inhabitants of the Mill Cottages at Tutsham to suffer from diarrhœa.

THERE IS GOOD WATER ALSO.

The central portion of the town most fortunately enjoys a totally different supply. In fact, there are three different supplies for the centre of Maidstone. The first is called the Broadley springs. They are reached by a heading into the chalk some three miles from the town and to the village of Boxley. The second supply comes from the Cassington springs and consists of chalk waters gathered in the Cassington woods. The springs are at some distance from the town and at the foot of the North Downs. The third is termed the Conduit supply, and comes from high grounds within the town. It is not connected with the Maidstone Waterworks Company. About twelve months ago the medical officer of health found by chemical analysis that this water was accidentally polluted. The source of pollution was subsequently discovered and stopped, so that there is now no special reason to believe that this water has had any evil influence on the present epidemic.

All these facts, though very significant, are not so conclusive as the distribution of the disease itself. Taking the figures as they stood on Tuesday evening 319 cases of typhoid fever had been notified from the north-eastern part of the town which receives the Farleigh water-supply. From the south-eastern district, where the same water is drunk, there were 111 cases. Finally, in the western district, which is also dependent on the Farleigh water, there were 392 cases of fever. On the other hand, in the centre of the town, where the Boxley, Cassington, and Conduit waters are distributed, there were only 24 cases. This contrast is all the more remarkable as the population is much more dense in the central than in the other districts of Maidstone.

THE FIGHT AGAINST THE EPIDEMIC.

Considering the rapidity with which the epidemic has spread and the trouble and sudden strain upon the authorities there has not been much time for investigating the causes. The most urgent matter at present is to deal with the evil itself, and for this purpose the hospital accommodation has proved altogether insufficient. Maidstone boasts of being a pioneer town in the creating of an infectious diseases hospital, and one wing of the fever hospital was at once set aside for the typhoid cases. This contains twelve beds. On Sept. 21st a system of district nursing was organised, and a number of trained nurses brought down from London. There were then thirty-six nurses in Maidstone, but so many more have come since then that the medical officer frankly confessed he had lost the record. In the streets nurses are seen hurrying to and fro in all directions, and seem as numerous as the soldiers in a German town. On Sept. 24th an emergency hospital was opened near the Chatham and Dover Railway Station which contains thirty beds. The hall of the Salvation Army is now being hastily fitted up with forty beds and will soon be available. But so widespread is the epidemic that all this is still insufficient. Special care has

Digitized by Google

been taken to flush the sewers, and the sanitary authorities have themselves flushed all the house drains where there are cases of typhoid fever; but there will have to be a big fight by-and-by between the authorities and the householders to compel the latter to put their drains in order.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Mason College.

THE winter session of Mason College is to be opened on Oct. 1st, on which occasion an address will be delivered by Sir J. Crichton-Browne. It is expected that a large audience will avail themselves of the opportunity of being present. The conversazione of the evening allows the meeting of old friends and students, the seeing and hearing of new things, in addition to other Athenian attributes. Hitherto similar occasions have always been most successful. The Faculties of Arts and Sciences hold their inaugural meeting on Sept. 30th.

Knowledge is Power.

Happening to be passing through the surgical casualty room of a large hospital in the town the house surgeon pointed out to me a case of somewhat trivial injury he had just attended. The patient on entering the room displayed prominently his badge of the Ambulance Cross, and in answer to inquiry as to what was the matter said it was an accident—"I have met with an abrasion of the epidermis." No wonder the house surgeon was taken aback and that the patients around looked with awe upon the latest comer, who could state his own case in such profound terms.

A Large Order.

At a recent inquest the city coroner, Mr. I. Bradley, commenting upon the insanitary condition of certain courts, remarked that one-fourth of Birmingham ought to be demolished. No doubt the state of certain areas is as bad as can be, and that they are highly unsuitable as dwellings for human beings no intelligent person would deny. But are we worse than other large towns? And if these dilapidated tenements are pulled down, will not the poor and the vicious flock to other quarters and continue the same habits?

The Meeting at Montreal.

Birmingham was well represented at the meeting of the British Medical Association at Montreal. Honours were distributed sparingly to those of the administrative body, an honorary D.C.L. falling to Dr. Saundby as president of the council. Those who have returned safely express different opinions as to the effect of so long a journey. "Never again," is the remark of a veteran practitioner, while others who have braved the perils of the sea without its accompanying sickness express their appreciation of the hospitality and friendliness of their reception.

Sept. 28th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Chat Moss.

THIS estate of 2600 acres was purchased by the Manchester City Council in August, 1895, at a cost, including legal expenses, of £139,350. At that time almost the whole of it was held by various persons on leases which only expired last February, so that the Health Committee, for whose requirements it was bought, can only be said to have had possession for about six months. The original ninety years leaseholders drained a large part of the moss, and 1900 acres are already under cultivation; 400 acres, really outside the moss, have long been in agricultural use, and there are only about 200 acres of wild moss still left in their natural condition. Some portions have been planted and form good pheasant cover. Manchester was fortunate in being able to obtain this large area of land for the disposal of its many thousands of tons of garbage and night-soil. Carrington Moss of 1100 acres is still available for about twenty tons per acre annually, but from a return prepared in 1893 more than 315,000 tons have to be dealt with, so that enough is left for Chat Moss, which it is calculated can take thirty tons per acre for a long time to come. The extent of the latter moss can perhaps be more easily realised by stating that it is 3½ miles long by 2¼ broad than by merely giving the number of acres. Its eastern boundary is 5½ miles from the Manchester Exchange. The carriage and distribution of heavy and cumbrous material such as night-soil are serious considerations, but fortunately the Ship Canal is easily available for the purpose, and barges or steamers can be sent direct from the corporation yard in Manchester to the wharf near the edge of the moss. From this point a light railway will be constructed to the moss, and branches will run to different points as required. It is said that the entire outlay on the 2600 acres will scarcely reach £208,000. Manure will be laid down practically at the field gates at a cost to the farmer of about 1*s.* 3*d.* a ton. The carriage will cost about 1*s.*, so that the city will receive 3*d.* a ton for ridding itself of a nuisance which at Chat Moss is a valuable manure. These changes are eagerly looked forward to by the smaller farmers, who already produce immense quantities of vegetable produce of all kinds. When the light railway is completed 50,000 tons may be put on the land every year. The spongy, shifting moss has a depth in places of more than 30 feet, but in some parts, where it is shallower, cottages—or rather shanties of wood planked together—have been built. The sinking of the moss has curiously twisted them; here and there the floors have disappeared, and in some instances the conditions as to sanitation are deplorable. New houses and cottages are being built. Creasoted baulks of timber are laid transversely on the face of the moss as a foundation. Above these a stout beam of oak is laid lengthwise and on this the brickwork is raised. Pipes connected with the Manchester water-supply have been laid, so that the use of the bog water is no longer a necessity. It is believed with good reason that the purchase of Chat Moss will be a pecuniary and sanitary success which will contrast favourably with the culvert scheme.

Evening Continuation Schools.

A resolution was passed at the last meeting of the Manchester School Board appointing a sub-committee to consider the question of special instruction for the large number of dull and defective children to be found in Manchester. In the course of the discussion an important matter was brought up, the attendance of day scholars at night schools. In a recent speech the deputy-chairman, Mr. E. J. Broadfield, stated that "another more recent concession was the permission for pupils in the higher grades of the day-schools to earn more grants in the night-schools." This idea that the children are to be used as grant-earning machines for the schools will not appeal to our sense of the purposes of education. The Rev. Canon Nunn said that last year the number of day scholars on the books of the evening schools was 3731. They attended school three times a day, which, he contended, was bad for them. Beyond the injury to the children themselves there was the over-pressure to the teachers. He knew of one case where a child was attacked with epilepsy, and was told such cases were on the increase. In a letter to the papers he corrected this statement, the case being one of chorea, not epilepsy. Dr. Woodcock contended that there was no evidence of any injury to the children. In a letter to the *Courier* endorsing the Rev. Canon Nunn's views Mr. T. Gavan Duffy gives one instance of which he had personal knowledge, in which a bright boy attended a board school where, "in addition to the essentials of elementary education, they crammed him with algebra, mensuration, French and German, the theory of sound, light, and heat, and magnetism and electricity. After school hours he was compelled to spend an hour and a half every evening practising on a piano, and at night he attended (in the winter) a shorthand class in connexion with the evening continuation schools." This brilliant boy, he says, "is now at the age of fifteen an imbecile," and no great wonder. It is probable that when we consider the ill-developed physique and want of stamina of the major part of the population of our crowded manufacturing towns most of us will agree that day scholars will get more harm than good from attendance at night schools.

Juvenile Street Hawking.

All will agree with a resolution that the question of juvenile hawking should be brought to the notice of the Parliamentary Committee of the City Council, which was

Digitized by Google

proposed by Dr. Woodcock, seconded by the Rev. Canon Nunn, and carried unanimously.

The Owens College.

Dr. Arthur Harden, one or the Senior Demonstrators in Chemistry at the Owens College, has been appointed Lecturer in Chemistry at the British Institute of Preventive Medicine, London.

Meeting of Ratepayers on the Culvert Scheme.

Since writing of the meeting of the City Council, when the culvert scheme was adopted by a large majority of those present, but, however, not a majority of the whole council, a meeting of ratepayers has rejected the scheme by a large vote. In consequence of this the Lord Mayor, as chairman, formally demanded a poll of the citizens, which will take place towards the end of October. It is not certain, therefore, that the matter will be brought up again, as was intended, at the meeting of the council to be held to-morrow.

Sept. 28th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Unrestricted Sale of Opium by Druggists.

AT an inquest held in Dublin on the 27th ult. the city coroner made some strong remarks as to the present state of the law in reference to the sale of poisons such as laudanum. He considered, as he stated, that the practice of selling opium to any person without a physician's or surgeon's prescription was an exceedingly objectionable one and ought to be discontinued. It was stated at the inquest that the deceased, an old man, had asked at a druggist's shop for fourpennyworth of laudanum. He was supplied with five drachms of the drug, which he swallowed with fatal result. The coroner of Belfast had occasion some months ago to express similar strong strictures on the same subject in the case of a man who purchased sixpennyworth of laudanum at a druggist's and who was found dead in a carriage of the Belfast and Northern Counties Railway. In the instance of a man who was recently indicted in Dublin for having attempted to commit suicide, it appeared that the accused had bought an ounce of laudanum and was about to swallow it when he was forcibly prevented. Mr. M. J. O'Connell, pharmaceutical chemist, deposed that the full contents of the bottle if swallowed would probably have proved fatal. Mr. Justice O'Brien inquired whether there was no restraint on the sale of this kind of deadly poison, but was told that "it was not exactly a deadly poison." The information seemed to rather surprise the learned judge, who probably thought that laudanum had a sufficiently deadly reputation to fully justify his epithet.

New Regulations for Examination by the Apothecaries' Hall, Ireland.

The examinations in medicine, surgery, midwifery, and pharmacy under the new regulations have been announced to commence on Oct. 12th at the Apothecaries' Hall, Mary-street, Dublin.

The Royal Victoria Hospital, Belfast.

At a special meeting of the life governors and board of management of the Royal Hospital, held on Sept. 16th, the following resolution, as suggested by the "Relations Committee" of the new Royal Victoria Hospital, was passed by a majority: "That the board of management of the new Royal Victoria Hospital shall consist of the president, secretary, treasurer, and five members of the medical and surgical staff to be annually elected by the visiting staff; fifteen life governors, of whom three shall, if possible, be ladies; and fifteen governors, as hereinbefore defined, of whom three shall, if possible, be ladies; and that the said fifteen life governors and fifteen governors shall be elected on the said board by the said general committee." In order to render this resolution operative it is necessary to obtain the consent of each of the life governors (all of whom are *ipso facto* members of the board of management of the Royal Hospital), and a circular has just been issued to each of the life governors enclosing a form of assent for signature. The reasons which led the meeting to adopt this resolution are as follows: the number of life governors of the Royal Hospital is about 250, while at the same rate of qualification (viz., a minimum donation of £50) the number of subscribers to the Royal Victoria Hospital who will be entitled to become life governors will be about 400. When the two institutions become fused and incorporated under a new charter the total number of life governors will be about 600. Under the charter of the Royal Hospital all the life governors are *ex-officio* members of the board of management and entitled to attend its meetings and to vote, while under the charter of the Royal Victoria Hospital this privilege will not be conferred on the new life governors. It is clear that the attendance of 600 persons would be destructive of the possibility of performing such work as is required for the practical administration of the affairs of the corporation, and therefore the right granted by the old charter to the life governors of the Royal Hospital is to be withheld from persons qualifying as life governors of the Royal Victoria Hospital. But as it is equally clear that the creation of two different classes of life governors of the Royal Victoria Hospital, one being *ex-officio* members of the board of management, and the other not, would be highly objectionable, it has been decided to ask the life governors to voluntarily renounce this privilege. This board of management is to be elected for three years (one-third to retire annually). In the first and second year those to retire shall be selected by the board of management by ballot. In subsequent years those longest in office shall retire. Retiring members shall be eligible for re-election. The medical and surgical staff will be elected by this board of management. This will to a large extent do away with the great evil of canvassing for medical appointments, which at present is unavoidable.

Liability for Payment of Rent in Insanitary Houses.

A curious case came before the Belfast Recorder on Sept. 25th, when an occupier of a house was sued for three quarters' rent of the premises under an agreement for five years. A child of the occupier, it was alleged, died from the unsatisfactory state of the drainage, whereupon that person left the premises and returned the key, which the agent refused. It was for the rent of the period between this date and the end of the term of agreement that the process in law was brought. Two sanitary engineers who examined the house proved it was unfitted for human habitation, and a medical man said the child of the occupier died after four days' illness from a severe type of scarlet fever, the virulence of which was intensified by the presence of sewer gas. All the members of the household (except the occupier himself) had been affected with sore-throat, a condition often produced by sewer gas. The Recorder said it was plain from the evidence that the premises were not in a sanitary condition, but if a person took premises he took them as they stood. This was not like the case of a furnished house. If it was a furnished house that would be an implied covenant that they were fit for habitation and fit for the purpose for which they were let; but if a person took a house he did so with his eyes open, and if it was not in a sanitary condition it was for those who took the house to examine it. The occupier became bound to put the house if defective in a sanitary condition at his own expense. Neither the landlord nor agent was legally bound to put the house into a sanitary condition.

Hospital Saturday in Cork.

The annual collection in aid of the Cork hospitals took place last Saturday. There were several prophets of evil who foretold that it would be useless to hold it this year as such a large sum had been recently subscribed for the hospitals in connexion with the record reign celebration. However, it is gratifying to learn that the street collections were entirely successful and fell short by only a few shillings of what was realised last year. The sums collected in several large business concerns have not yet been handed in, but it is believed that the total amount will reflect credit on all concerned.

Appointment of Professor of Practice of Medicine in the Queen's College, Cork.

Dr. William Edward Ashley Cummins has been appointed by Royal warrant Professor of the Practice of Medicine in the Queen's College, Cork, in succession to the late Professor Edward Townsend. Dr. Cummins was a distinguished *alumnus* of the Cork College, and is a gold medalist of the Queen's University, where he graduated in the year 1879 with honours. He has been a member of the staff of the Cork Women and Children's Hospital for a number of years, and is also one of the physicians of the Cork Union Hospital.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Charge Against a Medical Man.

A RECENT incident connected with a medical man is causing great excitement in Paris at the present moment. A young practitioner, by name Laporte, thirty-three years of age, who had been living for a short time in a working-class quarter of Paris, entered his name with the police commissary as a *médecin de nuit*. Some days ago he was called at 3 A.M. by a policeman to attend a woman in labour, as the midwife in attendance was unable to deliver her and had consequently applied at the police station for a *médecin de nuit*. Dr. Laporte found himself confronted with a difficult case. The woman had had five previous confinements, and upon each occasion there was some complication, so that forceps or version had been employed. Dr. Laporte put on forceps, but could not deliver the head, which was very large. He then informed the husband that craniotomy would be necessary to save the mother's life. Having obtained his consent, he sent for some chloroform and put the patient under its influence with the aid of the midwife, but being without the necessary instruments he broke up the head with such as he had at hand—namely, a chisel and a hammer. The patient was safely delivered, and when day broke the midwife took her to the hospital, where two days afterwards she died. The hospital medical officer refused permission for the burial and this brought about the intervention of the police commissary, and the husband made a complaint to the authorities, accusing Dr. Laporte of having caused his wife's death. The judge cross-examined the practitioner, who gave a simple recital of the facts and declared that in view of the urgency of the case he had used such simple instruments as he found ready to his hand, quoting as authorities the example of Pajot and other accoucheurs of the old school. The judge upon this caused him to be arrested and imprisoned. This caused a great sensation among the medical men of Paris, for an accusation of homicide by imprudence never carries with it the right of arrest. A post-mortem examination was made of the body of the woman, and there were found sundry perforations into the rectum and the uterus. For two days the daily press was full of articles declaiming against the greediness of medical men and their negligence in not providing themselves with the necessary instruments. Afterwards, however, upon the inquiry being resumed it was discovered that the unfortunate Laporte was absolutely penniless, that he had entered into practice four years before as auxiliary surgeon to a shipping company, that he then tried to practise in a rich neighbourhood without, however, having any patients, then he moved into a more modest quarter and, still meeting with no success, when his money came to an end he moved into the working-class district of the Charonne, where he had been for fifteen days. On the evening of his arrest he had had no dinner, and there were only 75 centimes in his pocket. On the police searching his house there was found a file of a private journal, which was handed over to the journalists in accordance with the usual custom, and it was then found that the unfortunate man had fought for two years against poverty and, utterly broken down by the misfortunes so common at the present day among members of the medical profession, such as medical aid societies, bad debts, and having to give medicine for nothing, he entered his name at the police-station so as to get the 10 francs which are guaranteed for every visit made at the demand of the police by a *médecin du nuit*. Called out at the request of the midwife, he had done his best, and he had even proposed to the husband to remove the woman at once to the hospital, which offer, however, was refused; besides the head was already at the vulva, and moving her would not have been without danger. Public opinion then veered completely round, and all the papers began to pity the unfortunate medical man, while letters from various accoucheurs were published, declaring that considering the high price of the instruments necessary for craniotomy it was impossible for a medical man in such a poor quarter to possess them. The Association of Medical Men of the Seine appeared as a deputation before the judge, but without result, and the judge even used the strange argument that he considered that, as Dr. Laporte had no means, the best thing to do was to send him to prison. A committee offered to give bail for him, but the judge refused. So the affair stands, and it is the one topic of conversation, not only among the medical men of France, but among the Paris public, who have already commenced to side with the unfortunate medical man as against the judge.

Gunshot Wounds of the Abdomen.

M. Chauvel read a paper at the Academy of Medicine, following on some observations made by M. Caillet, a military surgeon, in which he contended that the surgeon, when confronted with gunshot wounds penetrating the abdomen ought immediately to perform laparotomy and look out for the various perforations of the viscera and see if he can close them, without waiting till peritonitis arises to force his hand. It is now known that projectiles of very small calibre cut holes in the muscular tissues so small that very often they cannot be traced, so that frequently a probe does not reveal their presence. This method of diagnosis, while it is of great value when it gives a positive result, has not, when it fails to do this, an equal importance. Despite various statistics which are opposed to hasty intervention, M. Chauvel declares that in penetrating wounds of the abdomen made by knife or sword, as well as by revolver bullets, immediate laparotomy is generally indicated.

The Pathogeny of Erratic Eruption of Wisdom Teeth.

M. Moty read a communication before the Academy of Medicine stating that in wisdom teeth extracted on account of erratic eruption there was always found at the level of their fangs a soft material, composed of epithelial cells, which could be washed out by a stream of water. M. Moty concludes that the various accidents in the eruption of the wisdom teeth are due to the inclusion of aberrant epithelial masses which represent rudimentary wisdom teeth. The term, "vicious evolution," which is habitually applied to this class of accidents is erroneous, and ought to be replaced by that of "supplementary dermoid of the wisdom teeth."

Intestinal Parasites in China.

At the same meeting of the Academy, M. Laveran read a paper upon a communication by M. Matignon, dealing with intestinal parasites. Oxyurides are very common in Pekin, as many as 95 per cent. of the children being affected by them, and ascarides are no less frequent in adults. Out of thirty patients who were treated with santonin, twenty-eight were found to harbour ascarides. These latter parasites arise from drinking water and from the use of vegetables which are frequently consumed raw, and which grow in fields where the Chinese practise sewage irrigation. On the other hand, among the Europeans who live in Pekin ascarides are very rare, because foreign residents mostly drink pure water and almost always cook the vegetables which they consume. M. Matignon reported two cases of suffocation in children owing to the presence of ascarides in the pharynx. Tapeworm was found in 20 per cent. of the Europeans who live in Pekin; among the Chinese it is very rare. Of twenty-five Chinamen taken at random and treated with "pelletierine" not one was found to suffer from tænia.

Sept. 29th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Fate of Dr. Maurizio Sacchi.

THE new issue of the "Bollettino della Società Geografica Italiana" has a deep, not to say dramatic, interest for the narrative it gives of the Bottego expedition and the light it throws on the fate of Dr. Maurizio Sacchi. There is now no doubt that the able and accomplished young medical explorer came by his death in the manner already described in THE LANCET.[1] It is a satisfaction to know that nothing was left untried to get authentic news of him and, if this gave reasonable hope of his still being alive, to rescue and bring him to a place of safety. The Italian Geographical Society in concert with the Government spared no effort to track him, and the instant it became known that he had parted company with the main body in October, 1896, the

Digitized by Google

Italian Ambassador in London and Italian Consul at Zanzibar made it their business to interest the British Government and the English resident at Zanzibar in pushing inquiries as to his movements through the medium of couriers and of the caravans traversing those regions. All this, and more, was done by the representatives of the two powers; and the upshot of the quest makes it clear that Dr. Sacchi, after the date mentioned, found his escort of twenty-five Ascars reduced by disease and death to five, and that the men of the Amhara tribe set upon the little band and killed the doctor, appropriating the ivory and other more precious material he had himself accumulated for his scientific report. The loss of this latter is to be deplored, not merely for its own sake, but for the evidence it would have afforded the contemporary world of how brave an explorer and how bright a nature-student has perished in young Maurizio Sacchi.

Honours to British Science.

Our "Accademia dei Lincei" (literally "Academy of the Lynx-eyed," the Italian equivalent to the London Royal Society), at its sitting on the 17th inst. elected a number of Fellows in the department of physical, mathematical, and natural science. Among these was the Cambridge Professor of Astronomy, Mr. G. H. Darwin, F.R.S., of Trinity. Again, in the moral, historical, and philological department there were two Fellows of English nationality elected: Dr. Thomas Hodgkin, D.C.L., author of "Italy and Her Invaders"; and the Right Hon. G. J. Goschen, M.P., First Lord of the Admiralty.

The Foundling Hospital Scandals: Official Report.

"The incredible scandals" given to the light in connexion with the Neapolitan Brefotrofio dell' Annunziata and with some at least of the foundling hospitals in the Venetian province, led, as THE LANCET announced, to an inquiry on the part of the Government into these institutions. The first of the reports issued under this mandate has just appeared, and it deals with the Brefotrofio of Padua. Its author is Dr. Natali, provincial medical officer. The document is a harrowing one, and I can well understand the "vivissima impressione" which, according to the *Veneto*, its publication has produced. The "accommodation" of the Paduan hospital Dr. Natali found to be worse than defective in every requirement of hygiene—"assolutamente inadatta allo scopo," and calling loudly for "pronti ed energici provvedimenti." One most reprehensible rule has hitherto, it seems, been rigorously enforced in the institution: "the nurses are never allowed to go beyond its walls, except in cases of urgent necessity and after special 'leave of absence' is obtained." Even under this latter regulation they must always be accompanied by a "custode." They are not even permitted to have an outing or an airing in the garden or shrubbery belonging to the Brefotrofio! The effect of this imprisonment on their health and on that of the wretched "esposti" (foundlings) to whom, three or four in number per diem, they give the breast, may be imagined. Nor does the artificial "allattamento" (milk-feeding) escape Dr. Natali's severest censure. Its results, he says, are "disastrosi." In the quinquennium 1892-96 there were 341 infants in the Paduan Brefotrofio "nourished" artificially, and of these there died 325—in other words, 94·20 per cent. As for the medical surveillance of the Brefotrofio it was "discharged" by one physician only, at a salary of 600 lire (£24) a year! For this "stipendio"—less than 10*s.* a week paid in depreciated Italian paper!—he had also on his hands the "servizio del carcere giudiziario" (the prison-service attached to the law-courts). Dr. Natali's revelations, startling though they be, are reckoned but an "antepasto" (whet) to the "banquet of horrors" shortly to be spread before the world by the report on the Neapolitan Brefotrofio dell' Annunziata.

Typhoid Fever in Milan—"A Conspiracy of Silence."

On the 14th inst. there died in Milan the eminent naval engineer, the Cavaliere Giuseppe Melisurgo, member of a noble Neapolitan family which has given more than one distinguished engineer, civil and military, to the public service. His funeral was an imposing one, attended by the *élite* of Milan, socially and scientifically, and made memorable by *oraisons funèbres* of exceptional power. All this is learned from the Milanese journals; but what they carefully leave unnoticed is the fact that the Cavaliere Melisurgo was one of many victims to the epidemic of typhoid fever that has for weeks past been raging in the Lombard capital; that he was (for purposes of isolation, I presume) an inmate of the Ospedale Maggiore, already full to repletion of similar cases; and that after treatment there he died. Since the warning given by THE LANCET (Sept. 4th, p. 625) against sojourning in Milan, owing to the severity of the epidemic of typhoid fever long prevalent, the Milanese journals have religiously kept silence as to the visitation in question, and for anything that the *Corriere della Sera* or the *Secolo*, for example, have to say of it, the city might have an absolutely clean bill of health. Now this, I submit, is dealing unfairly with the travelling world, for which Milan is a great *entrepôt*. I remember, shortly after one of the severe cholera epidemics which have of late years visited Naples, that, at a meeting of its Municipio, the then Syndic was thanked by his brother councillors for having kept dark the presence of the disease and so retained the usual number of foreign visitors who, if made cognisant of the situation, would have stayed away! Such unworthy tactics are hardly to be expected in a city so enlightened, so enterprising, so wealthy, so eminently representative of all that is most estimable in the young Italian kingdom as the Lombard capital. Imagine the *Times* in London, or the *Temps* in Paris, or the *Nord-Deutsche Allgemeine Zeitung* in Berlin, suppressing their reports of the daily progress of an epidemic so as not to scare the outside world away. Meanwhile it is a duty which THE LANCET owes to its readers to emphasise the fact that Milan is still the haunt of typhoid fever; that her water-supply, as to purity and quantity, has still to be placed under sound hygienic regulation; and that other cities along the well-known Brindisi route are quite unsafe for even the temporary sojourner owing to their want of insanitation and the inevitable results. Bologna, for example, is by no means exempt from the visitation so severely felt in Milan—indeed, the Bolognese province is at present suffering from typhoid fever in an aggravated form. "Molti e gravi casi di tifo" are reported from Minerbio, a local commune, and a medical commissioner is now on the spot inquiring into the origin of the outbreak and suggesting measures for arresting its diffusion.

Sept. 25th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Yellow Fever in New Orleans.

YELLOW FEVER, which has been very prevalent during the summer in some of the cities of the Central American States as well as in Havana, Cuba, has finally made its appearance at Ocean Springs, a watering-place on Mississippi Sound. It is believed to have reached this locality by the way of Ship Island, a station in the Gulf to which vessels resort for disinfection. Fever was at first attributed to dengue, and upwards of one hundred cases had appeared before the real cause was suspected. Several cases went from Ocean Springs to other localities, and thus spread the fever. One case in New Orleans was followed by several others. The coöperation of the local boards of health is now supplemented and greatly aided by the Marine Hospital Service. It is believed that the fever will be controlled by the combined influences of these sanitary authorities.

The Leper Island of Molokai.

Recent reports from the leper colony on the Island of Molokai furnish some interesting facts. It is the fifth in size of the Sandwich Island group, and was set apart by the Government of Hawaii for the isolation of lepers found among the population. The island contains 200,000 acres. Its surface is variegated by valleys and hills, the latter rising sometimes to the height of 2500 feet. The lepers do not occupy all the island, but only a grassy plain, ten miles in length, and varying from one to two miles in width on the north side of the island, and yet separated wholly from the rest of the island and its population by a precipice fully a thousand feet high, which can be scaled at only one point, and this is securely guarded. Despite their freedom from taxation and rent, their ample supplies of food and clothing, their abundant herds of cattle and horses, and their fertile fields which require so little labour, the lepers are virtually life prisoners, shut in by the ocean on one side and by the impassable mountain on the other. Most of the lepers are natives, but some foreigners are found among the colonists, and all who once come to this part of

Digitized by Google

Molokai, save to bring supplies or to inspect as the board of health twice each year, do so with the expectation of never returning. At a cost of some $10,000 per month the Hawaiian Government maintains this open-air leper hospital in order to perfectly quarantine, and thus finally stamp out, leprosy among the Sandwich Islanders. Vigilance is used to separate anyone who is suspected until it is definitely known whether or not he is a victim of the disease, and if so he is promptly exiled to the island. Children who are born of parents who are lepers, after passing a given age without showing any signs of the disease, are removed from Molokai and kept in confinement for a certain number of years so that they may neither contract the disease nor be the means of spreading it; then if found "clean" by the board of health they are permitted to go anywhere. Such children are educated at the expense of the Government. Thus, after thirty years the Government has the satisfaction of believing that effectual means have been devised for the care of unfortunate lepers in the most humane manner, while attempting to suppress the disease which was so threatening to the population and fair name of the Hawaiian Islands.

Immigration Figures for 1897.

The Immigration League publishes the following facts. The total immigration for the year 1897 was 230,832, being a decrease in 1897 of 112,435 as compared with 1896. The total number of illiterate in 1897 was 44,580, by far the largest percentage being from Austria, Hungary, Italy, Germany, and Scandinavia. The fact that immigration, which was 1·3 larger in 1895, has fallen in 1897 below that of 1895 is another illustration of the law that the number of immigrants depends upon the degree of industrial activity in this country. And this leads to two important conclusions: first, that immigration will increase again rapidly as business activity increases; and, second, that the present is the time when the immigration laws can be amended with the least hardship to immigrants and the least disturbance to the immigration service. In regard to European immigration in 1897 it may be noted that while the proportion of the total immigration from south-eastern Europe has not diminished, the proportion from north-western Europe, which was 52 per cent. in 1895 and 39 per cent. in 1896, is only 38 per cent. this year—a steady decline. Of immigrants from particular countries the Swiss, Scotch, and Portuguese have this year fallen below the number of 2000, while the Poles have increased again above that number. The proportion debarred and returned is steadily diminishing, having been 1 per cent. in 1896, and being 0·8 per cent. this year.

Establishing a Standard for Cream.

The official journal of the milk trade states that during 1896 there were received in New York city nine million quarts of cream—a daily average of nearly 25,000 quarts—and 320,000,000 quarts of milk. Cream comes to the city either in forty-quart tin cans or in glass bottles. According to its method of manufacture it is divided into two classes: gravity, or hand-skimmed, and machine or separator cream. The proportion of machine cream to the gravity is about ten to one. About one-half of the cream supply of New York is sold to families, the other half is sold to ice-cream factories, bakers, and confectioners. The gravity cream is largely taken by the ice-cream maker, restaurants, and hotels. Its fat contents varies, although the great bulk of it ranges from 12 to 16 per cent. The machine cream is separated from the milk by the use of some one of the several centrifugal separators. Nearly all the cream served to families is separator cream, and though brought to the city in forty-quart cans it is put into pint, half-pint, and quart bottles before delivery. The bottling process is now under the regulations of the Health Department, and must be done in such manner as to prevent contamination from dust or by other impurities. Most cream delivered in New York is at least seventy-two hours old before it reaches the city. Though the fat in the cream varies greatly there is no standard test as yet applied. The exact composition of the cream or creams is usually unknown both to the dealer or the purchaser. Every dealer knows practically how good a cream must be in appearance for his customers and secures from a wholesale dealer cream having about that appearance. Whatever the character of that cream the retail price at the milk stores is nearly the same, being about five times as much as milk. The sale of cream is absolutely without control or supervision. Anything passes as cream which the consumer is willing to accept, whether it contains 10, 15, 20, or 25 per cent. of fat. It is now proposed to establish a standard by which to determine the different qualities of cream based on the fat contents, and to pass an ordinance regulating the sale of cream accordingly.

Cruelty to Convicts.

It has been a practice in the State of Georgia of leasing convicts to private parties. The charge of great cruelty has frequently been made against those employing convicts. It has been found that the rate of mortality in private camps is double that in public camps. A recent investigation confirms these reports. In one camp thirty negroes and one white convict slept chained together in a room 15 ft. by 17 ft. with the window nailed up. In another camp forty-six negroes and fifteen whites slept in a room 19 ft. square and less than 8 ft. high. The Governor of the State contemplates pardoning all the convicts in private camps as the only way in which he can rescue them before the expiration of their terms.

Sept. 18th.

Obituary.

EDWARD MEACHAM, M.R.C.S. ENG., L.S.A.

MR. EDWARD MEACHAM, a medical man well-known and respected in Manchester, died at his house in Red Bank on the 18th inst. His career was rather remarkable. He was born in London in 1824 and went to Manchester in 1846, where he was appointed labour master for the Chorlton Union. For many years he was occupied in missionary and philanthropic work in the poorest and most squalid districts of Manchester, and resolved to study medicine in order to augment his means of usefulness to the poor. He threw himself into this new task with characteristic earnestness and zeal, undeterred by the fact that the days of early manhood were passed. He became a Member of the Royal College of Surgeons of England in 1857 and Licentiate of the Society of Apothecaries in 1862, and for thirty years was Poor-law medical officer of the St. George's district. Nearly thirty years ago he established the Manchester Medical Mission, of which he was superintendent. Living among the poor and for the poor, his life may be said to have been spent in their service. He was not a strong man, but he showed much energy in, and great devotion to, his work. Of comparatively humble origin, traces of which he retained, and with few personal wants, a very moderate income sufficed him, and he worked for others, not seeking publicity. He was a "total abstainer," and no doubt found his efforts in aid of temperance in a district like Red Bank and Angel Meadow more impressive from his own example. He was a member of the Manchester Medical Society and the Manchester Medico-Ethical Association, and was formerly for a short time surgeon of the General Hospital for Sick Children. He was sincerely respected by his medical brethren. A pathetic addition to the story is that his wife, who had always sympathised with him in his work, died four days after her husband.

H. H. J. STERLING, M.R.C.S. ENG., L.S.A., R.N.

MR. STERLING was educated at the Royal Naval School, New Cross, and afterwards became a pupil of the late Dr. Jones, a physician to the Metropolitan Free Hospital. Mr. Sterling matriculated at the London University with honours and studied medicine at University College. After passing College and Hall he entered the Royal Navy in 1860 as assistant surgeon. He served on H.M.S. *Adventure* and *Hibernia*. A few years after he was invalided from the service and retired on a pension. Mr. Sterling's state of health prevented him from undertaking the arduous duties of active private practice, and he lived a quiet, retired, and studious life. He died on Sept. 11th, aged sixty years.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men have been announced:—Dr. Rudolf Berlin, Professor of Ophthalmology in Rostock and Rector of the University, died at Linthal, in Switzerland, on Sept. 12th, at the age of

Digitized by Google

sixty-four years. He was in early life assistant to Arnold Pagenstecher and for a time also in the surgical clinic in Tübingen. He was afterwards appointed Professor of Comparative Ophthalmology at the Veterinary School in Stuttgart. In 1890 he was appointed to the chair in Rostock in succession to Professor von Zehender. Numerous papers on ophthalmological subjects have appeared from his pen.—Dr. J. Brasseur, formerly connected with the *Gazette Médicale* of Liége, and President of the Liége Medical Union.

Medical News.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—At the College of Medicine, Newcastle-upon-Tyne, in the third examination for the degree of Bachelor of Medicine, the following candidates have satisfied the examiners:—

Second-class Honours.—Claudia Anita Prout Rowse, London School of Medicine for Women, and Francis Pope, Mason College, Birmingham.

Pass List.—Wilfred Frank Burn, Henry Coxon Coxon, and Leopold Stanley Davison, College of Medicine, Newcastle-upon-Tyne; Selina Fitzherbert Fox, London School of Medicine for Women; Edward Gofton, William John Harrison, James Andrew Hartigan, and Lawrence Fielder Hemmans, College of Medicine, Newcastle-upon-Tyne; Herbert George Harris, St. Bartholomew's Hospital; John Tyrer Johnson, College of Medicine, Newcastle-upon-Tyne; Margaret Joyce, London School of Medicine for Women; Ralph Albert Rogers Lankester, University College, London; Robert Fletcher Moorshead, University College, Bristol; Robert Atkinson Morland, Guy Broughan Picton, and Norcliffe Roberts, College of Medicine, Newcastle-upon-Tyne; Harold Robert Dacre Spitta, St. George's Hospital, and Carl Wahlgren von Bergen, College of Medicine, Newcastle-upon-Tyne.

FOREIGN UNIVERSITY INTELLIGENCE.—*Jena:* Dr. Ferdinand Gumprecht has been appointed Extraordinary Professor of Forensic Medicine.—*Giessen:* The University Medical Museum has received a valuable collection of skulls from Dr. von Hölder, of Stuttgart.—*Tübingen:* Dr. Winternitz, *privat-docent* of Midwifery and Gynæcology, has been granted the title of Professor.—*Vienna:* Dr. Haberda has for the present taken charge of the Forensic Medicine Institute, in place of the late Professor E. von Hofmann.

FOOTBALL CASUALTIES.—On Saturday last the following accidents occurred. In a match, Ardsley Parish against Barnsley Reserve, the Barnsley goal-keeper fractured his leg.—A young man, aged twenty-five years, while playing at Bolling Hall, Bradford, fractured his ankle.—At Farnham during a match a player of the Farnham club fractured his left ankle.—At Warwick a young man, playing for Warwick Victoria's Reserves against Coventry St. George's, broke his leg, and a player (right wing of the Warwick United) fractured his humerus.—In the course of a match played on Durdham Down, Clifton, between Redland Grove College and Westbury Park, a member of the former team, aged fifteen years, was struck on the side of the head with the ball. He continued for a short time to take part in the game, when he complained of illness and retired. Death occurred some few hours later. At the inquest held on Sept. 27th the medical attendant stated that he was of opinion that an artery of the brain had been partially ruptured.

LITERARY INTELLIGENCE.—The October list of the Religious Tract Society contains the names of several books of unusual interest. "Pictures of Southern China," from the pen of the Rev. James Macgowan, of Amoy, sketches the prominent features of daily life in Shanghai, Foochow, Kushan, Amoy, Swatow, Hong Kong, and Canton. "Old Samoa; or, Flotsam and Jetsam from the Pacific Ocean," is a book possessing considerable ethnological value. It is written by the Rev. J. B. Stair, who spent the years 1838-1845 in Samoa. "Philip Melanchthon," by the late Rev. George Wilson, M.A., is a sketch of the life and character and influence of the great Reformation theologian. Its appearance this year is a timely recognition of the fact that four centuries have passed away since the birth of the great friend of Luther. On Oct. 18th the society will publish a work from the pen of the Bishop of London. It is entitled "The Story of Some English Shires," and consists of seventeen chapters, each dealing with a separate county. The bishop's aim has been to produce not merely a series of historical sketches, but he has attempted to show that "places have characters of their own as much as men."

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.—At a meeting of the council of this College, held at Cardiff on Sept. 24th, Mr. H. Spencer Harrison was appointed Demonstrator and Assistant Lecturer in Biology for a period of three years.

MEDICAL MAGISTRATES.—Mr. R. Smith, L.R.C.P., L.R.C.S., F.R.C.S. Edin., and Mr. Caleb Joyce, M.B. Melb., have been appointed Justices of the Peace for the districts of Carnarvon and Beaconsfield, Tasmania, respectively.

MEASLES AT ST. ASAPH.—The National and Roman Catholic schools at St. Asaph were closed on Sept. 20th owing to an epidemic of measles. The schools at Bagillt and Greenfield have also been closed through the same cause. A conference of local authorities is to be held at Flint to consider the subject of providing an isolation hospital for the northern part of the county.

PAUPERS' JAM AT BEDWELLTY.—At the last meeting of the Bedwellty board of guardians attention was drawn to an entry made in the report-book by the medical officer that the jam supplied to the inmates of the workhouse was very inferior. The chairman remarked that this was not to be wondered at considering that "the mixture" cost only 2½*d.* per pound. The question was eventually referred to a committee.

PRESENTATIONS TO MEDICAL MEN.—Mr. J. M. Jones, L.R.C.P. Edin., L.F.P.S. Glasg., medical officer to the Chirk Castle Lodge of Oddfellows, has been the recipient of a handsome mahogany bookcase from the members of the club as a testimony of appreciation of his services.—Mr. John F. Wilkinson, M.B., Ch.B. Melb., Australia, on his leaving Bright, Victoria, after a residence of ten years, was entertained at a social meeting and presented with a purse of sovereigns by the residents of the district.

VACCINATION FEES.—At the meeting of the St. Thomas's (Exeter) board of guardians, held on Sept. 24th, a letter was read from Mr. J. D Shapland, M.R.C.S. Eng., L.S.A., public vaccinator for Exmouth, in reference to vaccination fees claimed by him. The clerk to the guardians said that the fees were for work done by Mr. Shapland's son, who was not authorised to act as deputy; the guardians could not, therefore, he added, legally pay the money, but the Local Government Board had, however, agreed to sanction the payment. After some discussion it was decided that the amount should be paid, subject to the sanction of the Local Government Board.

MEMORIAL TO A MEDICAL MAN.—On the 24th ult., at the Children's Hospital, Western Bank, Sheffield, Mrs. Cleaver formally presented to the institution a portrait of her late husband, Dr. Cleaver, who in his lifetime took great interest in the work of the hospital. In October last year the Lady Mayoress opened the new wing, part of the cost of the erection of which was defrayed by the Cleaver Memorial Fund—a fund formed to place in the hospital some permanent token of the late Dr. Cleaver's work. The amount realised was nearly £700. It will be an interesting connecting link between the early days of the institution and the future.

POISONING BY MORPHIA.—On Sept. 21st an inquest was held in Bristol upon the body of a sailor, aged twenty-nine years, who had died from the effects of morphia-poisoning. The evidence showed that on Sept. 18th the deceased was intoxicated, and his brother, who was on affectionate terms with him, wishing to quiet him, gave him nine grains of morphia in some beer, being under the impression that by administering the morphia with the beer "its strength would be diluted." The deceased appeared to have taken the morphia about 10 P.M., and about midnight a medical man was sent for, but in spite of every effort being used death occurred at 7 A.M. on Sept. 19th. The deceased's brother had taken the morphia from the surgery of a veterinary surgeon where he was employed as a servant. The jury returned a verdict of manslaughter.

NATIONAL REGISTRATION OF PLUMBERS.—At the Annual Congress of the Scottish Councils held at Perth on Sept. 24th Dr. Farquharson, M.P., was the chief speaker. He contended that the Plumbers' Registration Bill, so far from creating a monopoly, would tend to raise the status of plumbers. Professor Hay, medical officer of health, Aberdeen, likewise spoke in favour of the measure.

THE CINEMATOGRAPH PRIZE FIGHT AT THE AQUARIUM.—Those who believe that in America alone are to be found the more brutal pastimes of undegenerate England in the period conveniently covered by the Greville Memoirs cannot do better than visit the latest exhibition of the cinematograph at the Westminster Aquarium. On a series of films two miles in length is unrolled the great fight between Fitzsimmons and Corbett. As a performance which had the added glamour of illegality the contest is distinctly disappointing. To the uninitiated prize-fighting seems, if not so safe a pastime as cricket, far less dangerous than football, and the most neurotic journalist could describe it without a quiver of his pen. Messrs. Fitzsimmons and Corbett are not the bruisers of caricature and tradition, and their figures suggest the Apollo Belvidere rather than the Farnese Hercules, while the etiquette of the ring is as stringent as at a *partie* of piquet. As it is the shadow and not the substance we are asked to visit we can only admit that the Aquarium has secured one of the most wonderful feats of which the new entrancing toy is capable. The illusion of movement is far more perfect than it appeared a few months ago; quick action no longer jerks. Success has not been achieved in getting rid of the unpleasant noise of the instrument or in steadying the whole image, so the spectator has the feeling of witnessing the scene from a jolting railway carriage. The improvement, however, is none the less marked, and to the Aquarium belongs the credit of proving that cinematography is no longer in its infancy.

VITAL STATISTICS OF SOUTH AUSTRALIA.—The annual report of the Registrar-General of births, deaths, and marriages in South Australia for the year 1896 shows that on Dec. 31st, 1896, the estimated population of the province, exclusive of the inhabitants of the Northern Territory and of aborigines, was 355,286—viz., 182,185 males and 173 101 females. The births registered in 1896 numbered 10,012, being fewer by 525 than those recorded in the previous year. Of the total births registered 5085 were male births and 4927 female, the proportion of the former to 100 of the latter being 103·21. The birth-rate per 1000 of the mean population was 28·46, against 30·23 in 1895. The births entered in 1896 as illegitimate numbered 346 (173 males and 173 females), against 330 in the previous year. The percentage of illegitimate births to the total births registered during the year was 3·46, which compares with 3·13 in 1895, and is the highest rate since 1881. The deaths registered in 1896 numbered 4038, being more by 117 than those of the previous year. The deaths of males were 2121 and of females 1917, the proportion of the former to 100 of the latter being 110·64. The death-rate per 1000 of the mean population was 11·48, against 11·25 in the previous year; in every one of the twelve years 1885–96 the death-rate was low. The deaths assigned to "miasmatic diseases" numbered 195, as follows: Scarlet fever, 4; influenza, 59; whooping-cough, 17; diphtheria, 21; simple or ill-defined fever, 1; and enteric fever, 93. "Diarrhœal diseases" included 10 deaths from simple cholera and 244 from "diarrhœa, dysentery." Under "septic diseases" there were entered 29 deaths from erysipelas, 22 from "pyæmia, septicæmia," and 48 from puerperal fever. There was no death from small-pox or intermittent fever. Arranged in order of fatality the causes of death in persons above five years of age stand as follows, the first being the highest: old age, 317; phthisis, 304; diseases of the circulatory system (chiefly of the heart) not separately classed, 248; cancer, malignant disease, 185; pneumonia, 147; and apoplexy, 103. Of those who succumbed to "old age" none were under sixty years and 14 were ninety-five years and upwards. The marriages registered in 1896 numbered 2182, being more by 135 than those of the previous year, and being the highest number recorded in any year since 1891. The marriage-rate (that is, the rate of marriages, not of persons married) per 1000 of the mean population was 6·20, against 5 88 in 1895. The estimated population of the Northern Territory (exclusive of aborigines) consisted on Dec. 31st, 1896, of 4514 males and 420 females, among whom during the year 1896 there were 43 deaths of males, 2 deaths of females, 36 births, and 1 marriage.

Appointments.

Successful Applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ADAM, B. J., M.B., Ch.M. has been appointed Officer of Health for the North and and West Ridings of Ripon Shire, Victoria, Australia' vice J. Johnston.

COOK, P. R., M.B., Ch.B. Univ. New Zealand, has been appointed a Public Vaccinator for the district of Pelorus, New Zealand.

DAVIES, John Edwd. H., M.R.C.S.Eng., L.R.C.P. L.S.A. Lond., has been appointed Honorary Surgeon to Wrexham Infirmary; also Medical Officer of Health, Northern Division, Wrexham Rural District Council; also Medical Officer to Wrexham Fever Hospital, and Certifying Factory Surgeon, Wrexham District.

DUNCAN, J., M.B., Ch.M. Aberd., has been appointed a Public Vaccinator at Bairnsdale, Victoria, Australia, vice J. C. Morgan.

FISHER, H. H., M.D. Lond., L.R.C.P., M.R.C.S., has been appointed Medical Officer for the No. 2 Sanitary District of the Milton Union.

FISHER, R. W., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Workhouse, and for the first sanitary district of the Westbury-on-Severn Union.

GOLDIE-SCOT, T., M.B. Edin., has been appointed Assistant Medical Officer to the Warneford Asylum, Oxford.

GOODE, A., M.B., B.S. Adel., has been appointed a Public Vaccinator for the Urban and Suburban District of Norseman, and for the Rural District of Dundas, Western Australia.

HANNIGAN, M. H., M.D., M.Ch. Irel., has been appointed Medical Officer for the seventh and eighth Sanitary Districts of the Stow Union.

HARGREAVES, W. H., L.R.C.P. Lond., M.R.C.S., has been appointed a Public Vaccinator for the district of Akaroa, New Zealand.

HARRIS, L. H. L., M.B., Ch.M. Syd., has been appointed Senior Medical Officer to the Sydney Hospital, New South Wales, vice W. C. McClelland.

HAWKES, J. A., M.B. Melb., has been appointed Officer of Health for Kara Kara Shire, Victoria, Australia, vice J. D. Collier, resigned.

HERRIOT, S., L.R.C.P., L.R.C.S. Edin., has been appointed Health Officer for Bulong, West Australia.

HITCHINGS, R., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Workhouse of the Headington Union.

JOHNSTON, J. C., M.B., Ch.M. Edin., has been appointed Health Officer and Superintendent of the Quarantine Station, Point Nepean, Victoria, Australia.

LAING, J. A., M.B., M.S. Edin., has been appointed a Public Vaccinator for the district of Gisborne, New Zealand.

LANCASTER, L. B., M.B. Syd., has been re-appointed Resident Medical Officer to the Sydney Hospital, New South Wales.

LANE, H. A., L.R.C.P. Lond., M.R.C.S., has been appointed Resident Assistant Medical Officer for the Workhouse of the Chorlton Union.

LONG, WM. J., M.B., Ch.B. Melb., has been appointed an Honorary Medical Officer to the Hospital at Bendigo, Victoria, Australia.

MACDONALD, A., M.D., C. Penn., U.S.A., has been appointed Officer of Health for the Denison and Rosedale Ridings of Rosedale Shire, Victoria, Australia, vice V. E. Browne, resigned.

MARMION, E. J., M.B. Dubl., L.F.P.S. Glasg., has been appointed Medical Officer for the Workhouse of the Milton Union.

MORTON, W. A., M.B., Ch.B. Melb., has been appointed a Public Vaccinator at Outtrim and Jumbunna, Victoria, Australia, vice W. W. Hearne, resigned.

NEAVE, EDWARD F. M., M.B., Ch.B. Edin., has been appointed a Resident Medical Assistant to the Dundee Royal Infirmary.

PEEDLES, F. M., M.B. Melb., has been appointed an Honorary Medical Officer to the Hospital at Bendigo, Victoria, Australia.

PENFOLD, O., M.R.C.S., L.S.A. Lond., has been appointed President of the Local School of Mines, Bendigo, Victoria, Australia, and an Honorary Medical Officer to the Hospital at Bendigo, Victoria.

RENNIE, G. E., M.D. Lond., M.R.C.S., has been appointed Deputy-Coroner for the City of Sydney, New South Wales.

SEYLER, C. A., B.Sc., F.I.C., F.C.S., has been appointed a Public Analyst by the Glamorgan County Council, vice Morgan, deceased.

SHIELDS, A., M.D. Edin., has been appointed a Medical Examiner of Patients in the Metropolitan Lunatic Asylum, Kew, Victoria, Australia.

SIMONS, C. N., L.R.C.S. Irel., L.S.A. Lond., has been appointed Acting Officer of Health for Bright Shire, Victoria, Australia, vice J. F. Wilkinson, resigned.

STEWART, WM., M.D. Edin., has been appointed Medical Officer for the Bacup No. 2 Sanitary District of the Haslingden Union.

THOMPSON, L. G., M.D., Ch.M. Aberd., L.R.C.P., L.R.C.S. Edin., has been appointed a Member of the Hospital Board of Management, Launceston, Tasmania, vice Dr. Hallowes, resigned.

VANCE, N. C. A., M.B., Ch.B. Melb., has been appointed Officer of Health for the East Riding of Melton Shire, Victoria, Australia, vice A. A. Johnston, resigned.

WYNNE, J. G., L.R.C.P., L.R.C.S. Edin., has been appointed an Honorary Medical Officer to the Hospital, Colac, Victoria, Australia.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN.—Out-patient Surgeon. Applications to the Honorary Secretary, Beechenhurst, Selly-hill, Birmingham.

CHELTENHAM GENERAL HOSPITAL.—Resident Surgeon for the Branch Dispensary, unmarried, or if married without family. Salary £180 per annum, with partly furnished house, coal, and gas.

COUNTY ASYLUM, Whittingham, Lancashire.—Assistant Medical Officer, unmarried. Salary £100 per annum, with prospect of increase, together with furnished apartments, board, attendance, and washing.

DUNDEE ROYAL LUNATIC ASYLUM.—Medical Assistant. Salary £100 per annum, with board, lodging, and washing.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident House Physicians. Also Resident Medical Officer and Assistant Resident Medical Officer. Salary £200 and £50 per annum respectively, both with board and residence.

LONDON THROAT HOSPITAL, Great Portland-street.—House Surgeon, non-resident. Honorarium, £25 per annum.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—House Physician and House Surgeon for six months. The House Physician and House Surgeon will each receive a salary at the rate of £40 a year.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART AND PARALYSIS, Soho-square, London.—Resident Medical Officer, for six months. Board, residence, laundry, and an honorarium of ten guineas.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Shoreditch, N.E.—Junior House Physician for six months. Salary £15 for that period, with board and residence.

PADDINGTON-GREEN CHILDREN'S HOSPITAL, London, W.—House Physician and House Surgeon for six months. Salary at the rate of £50 per annum, with board and residence.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN, Waterloo-road, London, S.E.—Resident Medical Officer, for one year. Salary £70 per annum, with board and residence in the hospital.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, London, E.C.—Resident Medical Officer for six months. Salary at the rate of £100 per annum, with furnished apartments, board, and washing.

SUSSEX COUNTY HOSPITAL, Brighton.—Fourth Resident Medical Officer, unmarried. Salary £30 per annum, with board, washing, and residence in the hospital.

THE RETREAT, York.—Junior Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing.

VICTORIA HOSPITAL FOR SICK CHILDREN, Queen's-road, Chelsea.—House Physician, for eight months. Honorarium at the rate of £50 per annum, with board and lodging in the hospital. Also House Surgeon for twelve months. Honorarium £50, with board, and lodging in the hospital.

Births, Marriages, and Deaths.

BIRTHS.

CLARK.—On Sept. 25th, at Norton-road, Hove, the wife of A. Desborough Clark, L.R.C.P., &c., Edin., of a daughter.

COATES.—On Sept. 24th, at Ingleside, Whalley Range, Manchester, the wife of William Coates, M.R.C.S., of a son.

HARRIS.—On Sept. 21st, at Holy Innocent's-road, Hornsey, N., the wife of E. Bernard Harris, M.R.C.S., L.R.C.P. Lond., L.S.A., of a son.

POWELL.—On Sept. 22nd, at Glenarm House, Upper Clapton, N.E., the wife of Herbert B. Powell, M.R.C.S., of a son.

ROWELL.—On Sept. 24th, at East Rudham, Norfolk, the wife of Herbert Ellis Rowell, L.R.C.P. Lond., M.R.C.S., of a daughter.

SPILSBURY.—On Sept. 24th, at Hogsthorpe, Lincolnshire, the wife of F. J. Spilsbury, L.R.C.P., of a daughter.

MARRIAGES.

BAKER—BODY.—On Sept. 22nd, at Emmanuel Church, Plymouth, by the Rev. George B. Berry, Herbert Stainer Baker, M.R.C.S., L.R.C.P. Lond., of Rushden, Northampton, younger son of the late George Philip Baker, of Portsmouth, to Minnie, daughter of John Bond and Marina Body, of Plymouth.

CANNOCK—BEER.—On Sept. 22nd, at St. Mary's Church, Balham, Charles Watkyn Cannock, L.F.P.S. Glasg., of Counser Villa, Balham, to Helen (Nellie), younger and only surviving daughter of William Beer, of Bitterne, Balham.

FEATHERSTONE—WILLS.—On Sept. 22nd, at the Parish Church, Chapel-en-le-Frith, Derbyshire, by the Rev. J. P Cort, Vicar of St. Anne's, assisted by the Vicar, the Rev. Dr. Given, and the Rev. W. H. Austwick, of St. Mary's, Higher Crumpsall, George W. Beaumont Featherstone, M.R.C.S. Eng., L.R.C P. Lond., of Chorlton-cum-Hardy, Manchester, eldest son of the late B. Featherstone, Esq., of Wandsworth Common, London, to Mary M. (May) Wills, eldest daughter of Charles J. Wills, Esq., of Bank Hall, Chapel-en-le-Frith.

PERRAM—MACLAINE.—On Sept. 23rd, at St. Mark's Church, Dundela, Belfast, Edward Arthur Perram, M.D., third son of the Rev. George J. Perram, M.A., Holmwood Lodge, Highgate, London, to Violet Frances, younger daughter of George Langtry MacLaine, Wandsworth House, Strandtown, Belfast.

WHEATLEY—THOMPSON.—On Sept. 29th, at All Saints', Upper Norwood, by the Rev. P. B. Power, M.A., formerly Vicar of Worthing, assisted by the Rev. J. Oakley Coles, Vicar of All Saints'; James Wheatley, M.D., son of Charles Wheatley, of Edgerton, Huddersfield, to Mary Elizabeth, only daughter of Charles H. Thompson, of Oaklands, Beulah-hill.

DEATHS.

BROGDEN.—At Lagos, West Coast of Africa, Marie Victoria Brogden formerly of St. Bartholomew's Hospital.

REID.—On Sept. 26th, at Migvie, Bournemouth, Duncan Reid, M.A., M.B., formerly of Aberdeenshire, aged 31 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

WARTY NIPPLES.

To the Editors of THE LANCET.

SIRS,—I beg the favour of a small space in THE LANCET to ventilate the above subject, and to ask advice as to the treatment or non-treatment of the condition. I have a patient, a primipara expecting her confinement at the end of October, and the other day she asked me to look at her nipples. I did so, and found the centre of each nipple occupied by a large wart. The top of the wart had died, and I easily pushed it off with my thumb, leaving a cup-shaped ulcer out of which hung long tendrils. A very small part round the edge of each nipple seemed healthy. The patient says that this growth and death of the warts has been going on for a year or two. Like an infant's cord after birth, the growths become black, then a dirty white, and then fall off. Now as my patient is within a month of her confinement, should anything be done in the way of cauterising or otherwise? Again, should the patient be allowed to try to suckle the child? I should welcome any advice on those two points. Though in practice for over twenty years I have come across only one other case of the kind. It occurred in the practice of the late Professor Leishman, of Glasgow, whom some years ago I had the privilege of occasionally assisting. The whole of the left nipple was represented by a huge wart, but as the other nipple was quite healthy, it was decided to do nothing in the matter before the birth.

My patient is very anxious to be able to suckle, so I ask advice as to how her nipples may be put right by the end of October.

I am, Sirs, yours truly,

W. J. COLLYER ADAM, M.B., C.M. Glasg.

Acre Lane, Brixton West, Sept. 22nd, 1897.

Constant Reader (Southsea) has omitted to enclose his name and address.

Mr. F. W. Phipp.—A trace of permanganate of potassium.

ADVERTISING EXTRAORDINARY.

A CORRESPONDENT has sent us from Wolverhampton a very remarkable little pamphlet, one which we should refuse to believe had emanated from a member of the medical profession had it been possible to doubt it. It is entitled "Application to the Officers and Members for the Appointment of Medical Officer to the Great Western Railway Provident Society," and runs as follows:—

GENTLEMEN,—

It is with regret I hear of the resignation of DR. ELLIOT, your present medical officer. Since his successor will doubtless be elected after competition, I have allowed myself to be nominated as a candidate for the post; and in applying tender various reasons why my appointment would be of advantage to the Society.

The position of my surgery is central and near the Low Level Station. My practice is of a private nature, and not overburdened with ordinary club appointments: and being assisted by DR. H. CARTER MACTIER, who is highly qualified, being Bachelor of Medicine, Bachelor in Surgery, Bachelor in Midwifery, and Bachelor of Arts of the University of Dublin, and who has had excellent experience as House Surgeon in a large Dublin Hospital, and until lately was Resident House Surgeon to the Wolverhampton Eye Infirmary. I have appreciated his help in a department which is of great importance to railway employees—sight failure—which for want of skilled advice often leads to loss of position in your Company.

My personal experience before coming to Wolverhampton has been exceptionally and unusually practical and prominent. Successful as a student in obtaining various Honours, Medals, and Prizes, I was elected to the honorary post of House Physician in the Edinburgh Royal Infirmary, a most exclusive and enviable appointment; thereafter going abroad and spending some years in studying under the greatest Professors of the day in the Capitals of Austria, Germany, and in other foreign towns.

Your have on a previous occasion honoured my predecessor DR. BLANCH, with marked evidences of your esteem; and now I hope my efforts as a private practitioner will deserve even greater support. I only regret my knowledge of the election was rather delayed, thus debarring me the honour of addressing you, but I hope that that circumstance will not minimise the number of my supporters.

In the event of my election a branch surgery if required will be placed in a district selected by a majority of the members, also the Telephone may be available; and I promise to further the interests of your society in every possible way.

Vote gentlemen for **ability, efficiency,** and **experience.**

WILLIAM POLSON.

Bachelor of Medicine and Master in Surgery, University of Edinburgh.

Late House Physician, Royal Infirmary, Edinburgh.
Medallist in Medicine, Edinburgh.
First Prizeman in Public Health, Edinburgh.
Prizeman in Medical Jurisprudence, Edinburgh.
Honours in Midwifery.
Honours in Diseases of Women and Children.
Honours in Surgery.
Medical Referee for the Prudential Assurance Co.
,, ,, ,, Pearl ,, ,,
,, ,, ,, Mutual Reserve Fund Assurance Co.
,, ,, ,, Royal Liver ,, ,,
,, ,, ,, Royal London ,, ,,
,, ,, ,, British Workman ,, ,,
,, ,, ,, Pioneer ,, ,,
,, ,, ,, Edinburgh.
Medical Officer to Oddfellows, Caledonian Corks, and Brotherly Societies.

This letter, which was swollen into pamphlet shape by the addition of a photograph of Dr. William Polson in evening dress, cap, gown, and hood, and a cover on which that gentleman's name was printed in large capitals, is really a very extraordinary document to be published by a graduate in medicine, however keen his anxiety to secure an appointment. To our minds it is distinctly degrading for a practitioner to assure a lay audience that he is offering them *ability, efficiency,* and *experience.* Such statements when forming part of the advertisements of tradesmen are taken at their proper value, but it is an innovation for a medical man to employ trade methods with such frankness in the desire to get on, and we do not desire to compliment Dr. Polson on the departure. We recommend him, on the other hand, to beware of assuming publicly the attributes of ability and efficiency, however large his experience.

Dr. William Donovan, of Erdington, asks us to state that he is not the Dr. Donovan mentioned in our annotation last week entitled "Midwives."

THE MEDICAL STUDENT IN PARIS.

IN our recent Students' Number we published an article on the Cost of Medical Education which attracted the notice of the French press, many papers on the other side of the channel doing us the compliment of commenting upon the information contained in it. Naturally they compared the life of the student in London with that of the Paris student, and pointed out the absence in London of everything which could remotely resemble the famous "quartier Latin." In London there is no Sorbonne and no central college around which the universities and schools with their special *personnel* can cluster. Consequently the students scattered in groups round hospitals situated in widely separated areas are unable to leave their imprint upon any particular district, to hall-mark its cafés, to dictate to its music-halls, or, indeed, to impress themselves at all upon the community. *L'Autorité* concluded by stating that in Paris the life of a student is more costly than in London, while the prospect of early practice in Paris is even less to be envied. For "si des médecins anglais font des visites à un shilling, combien de jeunes docteurs français attendent leurs premiers clients pendant des mois et parfois des années!"

Sentiment.—From our correspondent's account it would seem that the second medical man who saw the child should have surrendered the case to him. But from the same account it is clear that this gentleman was more than usually awkwardly placed. We strongly advise our correspondent not to allow the matter to break his professional friendship with his brother practitioner.

"PEGAMOID."

WE have had brought to our notice a process which claims to render wall-papers, fabrics, &c., waterproof, germ-proof, dust-proof, and stain-proof. The process, which is called pegamoid, and gives its name to the articles thus treated, has been in use for some time, but it does not seem to be generally known, at any rate in England. As it may prove of importance from a sanitary point of view it may be well to direct the attention of our readers to the process. It consists in applying in a liquid form a composition which, after impregnating the fibres or pores of the material treated, solidifies. Ceiling- and wall-papers, as well as imitation leathers—which latter in some cases it is difficult to distinguish from the real article without minute examination—treated by this process can be washed with water and disinfected with strong disinfectants without in any way injuring the surface of the article treated. Even caustic soda seems to have little effect upon it except by boiling, and the only thing which has a deteriorating effect is alcohol. Wine and ordinary spirits, however, may be spilt upon pegamoid, but if washed off within a reasonable time prove unharmful. For upholstering purposes the process may have distinct advantages, and in the case of wall-papers it should prove of great importance, inasmuch as dirt and even ink-stains can be washed off with a wet mop. Wood, iron, and stone work can also be treated by this process in the form of paint. A silver paint which we have tried is washable and untarnishable. The address of the company is 144, Queen Victoria-street, E.C.

R. H.—A pamphlet written jointly by Mr. William Barnard, LL.B., and Mr. G. B. Stocker deals with the transfer of medical practices and allied questions. It is published by Stevens and Sons, 117, Chancery-lane. Mr. Percival Turner also treats of the subject of the purchase and sale of practices in his Guide to the Medical and Dental Professions, published by Baillière, Tindall, and Cox, King William-street, Strand.

Plumbism.—A [Departmental Committee was appointed by the Home Secretary in the spring of 1893 to inquire into the subject of "Industrial Lead Poisoning," and its report was presented to the House of Commons in December. A copy of the report could doubtless be procured from Messrs. Eyre [and Spottiswoode, East Harding-street, Fleet-street, E.C.

"AN URGENT APPEAL."

To the Editors of THE LANCET.

SIRS,—I have received the following subscriptions in addition to the sum already acknowledged in THE LANCET, bringing the total up to £10 19s. 6d.:—J. C., £1 1s.; A. P., 5s. The widow and eight children of the late Mr. Campe desire me to express their sincere gratitude to the members of the profession who have so generously helped them in their trouble, and may I thank you also for so kindly allowing the appeal to be made in THE LANCET.—I am, Sirs, yours faithfully,

WM. ASTLEY COOPER.

36, New-road, Rotherhithe, S.E., Sept. 22nd, 1897.

THE Diplôme d' Honneur has been awarded to "Vinolia" soap at the International Exhibition at Brussels.

THE INFLUENCE OF HEREDITY.

WE take the following passage from an interesting paper, headed "The Transformation of Heredity," which appeared from the pen of Dr. James G. Kiernan in a monthly magazine entitled *Medicine* published at Detroit, U.S.A. Zola would not have dared to imagine such things:—

"To illustrate how much may be gained by careful examination in this particular I shall cite some researches of my own pursued in regard to one family during more than two decades. The family originated in the Eastern States, but has branches south and westward. A farmer lived twenty miles distant from his nearest neighbour, whose only child he married. The daughter had led a lonely life till her courtship at the age of twenty-eight by the farmer, then three years younger. The farmer married her for $200 after having impregnated her. He then found lead on his farm and went to a city. A stock company bought his farm and launched him into the stock market, where he made money, more as cunning tool than adventurer. He became a high-liver, gouty and dyspeptic, and died from gouty kidney at the age of seventy. The couple had five children. The eldest, a son, became a 'Napoleon of Finance,' inherited his father's cunning, and died wealthy within the pale of the law. He married a society woman, the last scion of an old family. The second child, a daughter, was club-footed and early suffered from gouty tophi. She married a society man of old family who had cleft palate. The third child, a daughter, had congenital strabismus. She married a man who was suffering from irregular migraine. The fourth child, a daughter, was normal. She married a thirty-year-old active business man in whom ataxia developed a year after marriage. The fifth child, a son, was ataxic at eighteen. The scions of the 'Napoleon of Finance' and the society woman were an imbecile son, a hysteriac, a female epileptic who had a double uterus, a nymphomaniac, and a society man who wrote verses. The cleft-palated society man and club-footed woman had triplets born dead, and a strabismic migrainous son who, left penniless by his father, married his cousin, the nymphomaniac daughter of the 'Napoleon of Finance,' after being detected in an intrigue with her. The migrainous man and strabismic daughter of the farmer stock-broker had a sexual invert masculine daughter, a daughter subject to periodical epistaxis irrespective of menstruation as well as chorea during childhood, a normal daughter, a deaf-mute phthisical son, a cloacal daughter, an amelisc son, a cyclopic daughter born dead, and a normal son. The sexual invert married the versifier son of the 'Napoleon of Finance.' The progeny of the normal daughter of the farmer stock-broker and the ataxic man were a dead born sarcomatous son, a gouty son with early tophi, twin boys paralysed in infancy, twin girls (normal), a normal son, and a son ataxic at fourteen. The progeny of the nymphomaniac and her strabismic migrainous cousin were a ne'er-do-well, a periodical lunatic, a dipsomaniac daughter (who died of gastric cancer), deformed triplets who died at birth, an epileptic imbecile son, a hermaphrodite, a prostitute, a double monster born dead, a normal daughter, and a paranoiac son. The ne'er-do-well married his epistaxic cousin. The gouty son of the farmer's normal daughter married the hysteric daughter of the 'Napoleon of Finance.' They had a son born with unilateral asymmetry, a prostitute, dead triplets, a male sexual invert, a colour-blind daughter, and a normal son. The colour-blind daughter married a paranoiac grandson of the 'Napoleon of Finance.' The progeny of the sexual invert and the versifier (who were soon divorced) were a periodical nymphomaniac who had some artistic and literary talent, and a son who died of gastric cancer. The scions of the ne'er-do-well and the epistaxic woman were a moral imbecile, a 'bleeder,' a stammering daughter who had uvula deformity, a deaf-mute cryptorchid, dead-born triplets, an infantile paralytic son, and dead-born quadruplets. The progeny of the paranoiac and his colour-blind cousin were an exophthalmic daughter, an epileptic cryptorchid, a cleft-palated imbecile with a cloaca, dead-born quadruplets, an idiot boy, and a 'bleeder.'"

"A CASE OF HEMICHOREA WITH APHASIA."

To the Editors of THE LANCET.

SIRS,—With regard to the treatment of chorea I have seen many drugs used—choral, hyoscyamus, zinc sulphate and salicylate, and veratrine. I myself have never seen arsenic fail, although I have seen these other drugs fail to arrest the movements. We have at present a case of chorea in which salicylates were used for a fortnight without benefit. Recourse to arsenic is having a marked beneficial effect. With regard to the pathology of the disease I can only quote theories, as we are, and are likely to remain, in darkness, and our pathology is merely a suggestive pathology. Certainly the clinical features of the case seem to support embolic origin. Might we ask the question, What is the origin of chorea in cases in which no valvular lesion is present? Mimicry in childhood is a very strongly developed faculty, and why should a child not mimic the movements of chorea? They naturally excite interest, or shall I say curiosity, on the part of the child and might be compared to "habit spasms." Removal of a child to another ward will, we know, check these choreiform movements. I am, Sirs, yours faithfully,

Sept. 27th, 1897. S. J. ROSS.

THE SANITARY CONDITION OF HIGH WYCOMBE AND WYCOMBE MARSH.

WE have received a communication from the secretary of the High Wycombe Water Company, Limited, in reference to an annotation in THE LANCET of Sept. 18th on the above subject. The secretary, imagining that we were unaware of the existence of the company in question, furnishes us with some particulars in regard to it. The facts, however, related by Dr. Wheaton in his report to the Local Government Board on typhoid fever at High Wycombe were fresh in our minds when we remarked on the necessity for a pure water-supply to the *whole* of High Wycombe. We were aware that Dr. Wheaton had reported that the water-supply was derived "principally from wells," but that the company in question supplied a certain number of houses in the district. Concerning this company's supply, Dr. Wheaton says in his report, dated Aug. 20th, 1895: "A very small number of houses in Wycombe are supplied from this source; and even where the company's water is laid on it has frequently not been made to supply the closet." The secretary states that about 900 houses are now supplied by the company, so that even if no additional houses have been built since the last census there must, apparently, still be some 1800 houses supplied from the "extremely unsatisfactory" sources to which Dr. Wheaton referred.

Mr. G. Careles.—The following books may be found of use in addition to those we recommended last week: "The Art of Dispensing," published by the *Chemist and Druggist*; "Practical Dispensing for Students," by C. J. S. Thompson; "A Laboratory Course of Pharmacy and Materia Medica," by W. Elborne; "Lessons on Prescriptions and Prescribing," by W. H. Griffiths; and "Notes on Dispensing," by George Stirling.

Assistant.—It is a case for legal advice and probably legal interference. Assuming the facts to be as our correspondent states them he has our sympathies, while we do not see how his late principal can attempt to defend his behaviour.

Mr. E. Lyddon.—Our correspondent's remedy would seem to us to be to take legal proceedings against his traducer. Of course he would not do that without proper legal advice.

MEDICAL AID SOCIETIES.

To the Editors of THE LANCET.

SIRS,—In the town in which I live and carry on my professional work there exists a medical aid society registered under the Friendly Societies Acts. This medical aid society issues handbills from door to door informing the public that they can have medical and surgical aid on payment of 1*d.* per week for adults and ½*d.* per week for children. The medical officer is paid a fixed salary and is debarred from private practice, and he is to all intents and purposes a servant of the committee who carry on the business at a profit. If the medical officer left the service of the committee and decided to carry on medical aid work on his own account and issued handbills and placards as the committee now do, it is very probable that the Colleges whose diplomas he has or the General Medical Council would judge him to be guilty of infamous conduct in a professional respect. Is it fair or proper that a medical man cannot do on his own account work which a lay committee is allowed to do? If a medical man becomes the servant of a layman to do medical work his diploma will be cancelled by the General Medical Council; but if five or six laymen form themselves into a committee they are permitted with impunity to engage a qualified man's services and to enter into an agreement debarring him from private practice and from practising within a fixed radius after leaving their service. The whole thing appears to me to be such an anomaly and so grossly unjust that I believe the members of any other profession or calling would not submit to it for a single month. Can the General Medical Council or the Colleges find no remedy for this evil, which is rapidly growing, and which is driving many members of the profession into serfdom?

I am, Sirs, yours faithfully,

Sept, 27th, 1897. A LANCASHIRE SURGEON.

Mr. H. R. Tebboth.—The Roentgen rays have not yet been discovered sufficiently long for us to answer with any certainty. The depilatory effects of the rays have been stoutly denied by some observers and circumstantially affirmed by others, both in our columns and elsewhere. We recommend our correspondent to consult some of the writers.

M.B., C.M.—We refer our correspondent to an excellent article on the subject in the "Dictionary of Applied Chemistry," by Professor T. E. Thorpe, F.R.S., vol. ii., p. 177. Impurities in coal gas are dealt with under the Gasworks Clauses Act, 10 and 11 Vict., c. 15.

Mr. V. B. Clark.—The persons named in our correspondent's letter are not qualified English practitioners. We strongly recommend him not to consult them.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (4th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (5th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (6th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.).

THURSDAY (7th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.).

FRIDAY (8th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (9th).—Royal Free (9 A.M. and 2 P.M.), Middlesex, (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

WEDNESDAY (6th).—OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. F. J. McCann and others. Paper:—Mr. Alban Doran: On the Management of True and False Capsules in Ovariotomy.

FRIDAY (8th).—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.)—Dr. W. P. Herringham: Sudden Death in Rheumatic Fever due to Myocarditis.—Dr. W. H. White and Mr. J. Langton: Stricture of the Pylorus: Loretta's Operation.—Dr. A. G. Phear: A Case of Cerebral Sinus Thrombosis.—Mr. G. H. Makins: A Case of Œsophagotomy for the Extraction of a Tooth Plate, in which Cellular Emphysema developed in the Neck without Injury to the Pleura.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich-road, S.E.).—8.15 P.M. Annual Meeting. Election of Officers for 1897 98. Dr. G. H. Savage: The Insanities of Evolution and Dissolution. (Purvis Oration.)

LECTURES, ADDRESSES, DEMONSTRATIONS, ETC.

TUESDAY (5th).—GRESHAM COLLEGE (Basinghall-street, E.C.).—6 P.M. Dr. M. Symes Thompson: Preventive Medicine in the Victorian Era. (Gresham Lecture).

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Sir W. R. Gowers: The Neuron and Disease.

WEDNESDAY (6th).—GRESHAM COLLEGE (Basinghall-street, E.C.).—6 P.M. Dr. M. Symes Thompson: Preventive Medicine in the Victorian Era. (Gresham Lecture).

THURSDAY (7th).—GRESHAM COLLEGE (Basinghall-street, E.C.).—6 P.M. Dr. M. Symes Thompson: Preventive Medicine in the Victorian Era. (Gresham Lecture).

FRIDAY (8th).—GRESHAM COLLEGE (Basinghall-street, E.C.).—6 P.M. Dr. M. Symes Thompson: Preventive Medicine in the Victorian Era. (Gresham Lecture).

During the week marked copies of the following newspapers have been received:—*Bridlington Telegraph, Wolverhampton Chronicle, Sussex Daily News, Cambria Daily Leader, Glasgow Herald, Pioneer Mail, Times of India, Manchester Courier, Sheffield Evening Telegraph, East Anglian Daily Times, Liverpool Daily Post, Scotsman, Retford News, Devon Weekly Times, Builder, North Wilts Herald, Leeds Mercury, Birmingham Gazette, Western Morning News, Architect, Berkshire Chronicle, Dundee Advertiser, Isle of Wight Observer, Newcastle Chronicle, Westminster Gazette, Bristol Mercury, Edinburgh Evening News, North Wales Chronicle, Keene's Bath Journal, Midland Times, Yorkshire Post, Worcester Herald, Maryport News, Derbyshire Advertiser, Huddersfield Chronicle, Leicester Post, Sheffield Telegraph, Grantham Journal, Lincoln Gazette, Preston Guardian, Bury Times, East Devon Advertiser, Rugby Advertiser, Wilts County Mirror, North British Daily Mail, Hampshire Telegraph, Bedford Times, Brighton Gazette, Northampton Daily Chronicle, Local Government Chronicle, Weekly Free Press and Aberdeen Herald, Gazette (Montreal), Mining Journal, Hertfordshire Mercury, City Press, Local Government Journal, Public Health, Engineer, Surrey Advertiser, Guy's Hospital Gazette, Yorkshire Herald, Hong-Kong Weekly Press, Australasian Medical Gazette, Englishman (Calcutta), West Sussex County Times, Coventry Herald, West Middlesex Herald, Stowmarket Courier, Penarth Chronicle, &c., &c.*

An Address
ON
AUTHORITY IN AND OF MEDICINE.

Delivered in the Anatomical Theatre of the Medical School at Charing-cross Hospital on Oct. 4th, 1897,

BY WILLIAM CARTER, M.D., F.R.C.P. LOND., LL.B.,
PROFESSOR OF MATERIA MEDICA IN UNIVERSITY COLLEGE, LIVERPOOL.

GENTLEMEN,—Medicine, using that term in its broadest sense as including all that relates to the maintenance or restoration of health, owes much of the attraction which it exercises on those who study and practise it to its ever-increasing expansiveness. Looking back through the years that have passed since, as a student, I sat on the benches of this college I cannot but be struck with the marvellousness of the change which it has undergone during that period; and if we were endowed with the power of accurate anticipation as we are with that of retrospection, we should no doubt be as much astonished at the development which it will undergo during the coming thirty or forty years of its history as we now are with that which it has undergone during those just ending. Antiseptic surgery, with all its vast and splendid consequences to humanity; preventive medicine as a distinct and most fruitful branch of our profession; the proved relation of micro-organisms to some of the most virulent forms of infectious or contagious disease, with the subsequent discovery of methods of destroying these organisms without destroying the person in whose body they were multiplying, or of so modifying the character of the person's blood as to render him immune to their attacks; the determination of the influence of the internal secretions of some of the glands upon metabolic processes and the application of this fact to practice; the use of serum tests and serum therapy in the early recognition and cure of disease; the proved antagonism between the poison of acute rheumatism and salicin and its allies; these and many other achievements must rise instantly before the mind of every one of us.

Yet if all this had been foretold a century ago the prophet who proclaimed it would have been treated in the spirit in which true prophets always have been treated. He would not have been burned, because, happily, burning as a method of teaching truth or repressing error had long before gone out of fashion; but all that contemptuous sneers or cold indifference or open antagonism could do to break his heart or drown his voice would have been done, notwithstanding the supposed general enlightenment that characterised that, as it is thought to characterise this, age. In justification of this statement I will read to you a few words from a very remarkable prophecy, published just 103 years ago, which has earned for its distinguished author, even at the hands of biographers generally favourable to him, such appellations as "dreamer," "visionary," "benevolent enthusiast," "well-meaning mystic," &c., but never once that of a far-seeing, enlightened, philosophic seer. Condorcet—for he was the prophet—was being hunted to his death by the merciless agents of the Convention, yet undismayed by the terrors in the midst of which he was living he employed the last few weeks of his life, not in bemoaning his fate or vainly quarrelling with his times, but in looking forward with the clear and undimmed vision of a scientific prophet to a happier era which was even then he believed showing signs of dawning for humanity, and in his "Esquisse d'une tableau historique des progrès de l'esprit humain," wrote down what he saw. I will quote one passage, which runs as follows: "The organic perfectibility or deterioration of the classes of the vegetable or species of the animal kingdom may be regarded as one of the general laws of nature. This law extends itself to the human race; and it cannot be doubted that the progress of the sanative art; that the use of more wholesome food, and more comfortable habitations; that a mode of life which shall develop the physical powers by exercise, without at the same time impairing them by excess; in fine, that the destruction of the two most active causes of deterioration, penury and wretchedness on the one hand, and enormous wealth on the other, must necessarily tend to prolong the common duration of man's existence, and secure him a more constant health and a more robust constitution. It is manifest that the improvement of the practice of medicine, become more efficacious in consequence of the progress of reason and the social order, must in the end put a period to transmissible or contagious disorders, as well as to those general maladies resulting from climate, aliments, and the nature of certain occupations. Nor would it be difficult to prove that this hope might be extended to almost every other malady of which it is probable we shall hereafter discover the most remote causes. Would it even be absurd to suppose this quality of melioration in the human species as susceptible of an indefinite advancement; to suppose that a period must one day arrive when death will be nothing more than the effect either of extraordinary accidents, or of the slow and gradual decay of the vital powers; and that the duration of the middle space, of the interval between the birth of man and this decay, will itself have no assignable limit? Certainly, man will not become immortal; but may not the distance between the moment in which he draws his first breath and the common term when, in the course of nature, without malady, without accident, he finds it impossible any longer to exist, be necessarily protracted?"

That we are far, very far, yet from the realisation of this magnificent vision of future happiness of man upon earth is, alas, too true, yet it is a significant fact that every step taken since it was proclaimed has been distinctly in the direction of its fulfilment and has been taken, moreover, under the direct inspiration and guidance of our professions and we have but to remember that only a very few years before it was uttered Louis XV. of France had died of malignant small-pox, as annually died many thousands of his and our fellow countrymen; that Jenner's great discovery had not been proclaimed and adopted; that Voltaire is said to have characterised medical men, from whom Condorcet hoped so much, as those who put medicines of which they knew little into stomachs of which they knew less; and that not one of those great recently discovered scientific truths, the application of which has been so fruitful of good to mankind, had been so much as thought of, in order to be struck with the boldness of the prevision and encouraged to hope for, and aid in, its progressive fulfilment.

Look but for a moment at a small part of what has been achieved in this country under one only of the heads enumerated by him—viz., the sanative art—since in 1844 the "Health of Towns Commission" clearly revealed the extent to which preventable diseases prevailed and the means best calculated to check them, and especially since the Public Health Acts of 1872 and 1875 mapped out the entire kingdom into workable subdivisions and placed each under the supervision of an educated medical man; think of what is implied by a fall in the death-rate, which then for the first time in our national history began, from 22·5 to 18·7 per 1000; think of cholera having been as effectually banished from our shores as plague has been; think of the fact that typhus fever, which not long ago caused many thousands of deaths annually, and an outbreak of which when I was a student of this hospital almost decimated some of its wards, being now so little known that probably not one out of ten young medical men has ever had an opportunity of seeing a case; think how Adulteration Acts have insured to the poor that wholesome food and clothing which unprincipled manufacturers in their greed of gain would have denied them; how insanitary houses are everywhere being condemned and destroyed and healthy habitations for the poor replacing them; how injurious trades and manufactures are being supervised and modified in such a way as to promote and not to destroy the health of those employed in them; how open spaces are provided for healthy and rational exercise; how at last something of the care and consideration long given to the production and maintenance of a perfect machinery is being legally enforced for preserving the lives and health of those who work it; and how that in every large city in this and every other civilised country great numbers of earnest, thoughtful, scientific members of our profession are devoting time, energy, and talent to an investigation of those remote causes of disease and the means of destroying them to which Condorcet referred, and you will be filled with hope and encouragement and with a determination that the legitimate influence which medical opinion and

Digitized by Google

practice ought to exercise on the affairs of the world shall never be diminished by anything that you will do. It requires but a very slight glance at modern society to see how enormous that influence is, and it should be (and if we are true to ourselves it must be) as much for the advantage of mankind as for that of our profession that it shall be maintained and extended. But what can we do? may be asked. The reply will entirely depend upon ourselves. Individually we may think ourselves small enough, but, as the old Latin proverb has it, small things massed together are no longer small "Nihil est aliud magnum quam multa minuta." But in that very limited sphere in which we move as individuals, as well as in the larger and national one occupied by our profession, the effect which we shall be able to produce will depend entirely on the respect which we can gain for our opinions among the thinking portion of mankind, who alone constitute its true rulers. It is to the subject of authority in and of medicine, then—in this sense of power controlling opinion owing to recognition of its supposed truth and justice—that I wish to direct your attention, for, happily for ourselves as a profession, we are but little restrained by the fetters of external authority. So large, indeed, is the measure of freedom granted to us that extraordinary individual whims and extravagances are not unfrequently manifested within our ranks, which, however, by being wisely let alone or, at any rate, controlled only by the general body of wholesome opinion that prevails amongst us and is reflected with great clearness and strength in the medical press, are seldom, if ever, developed into extensively organised systems. Such whims seem to be one of the necessary inconveniences of liberty and part of the price that has everywhere to be paid for it. Yet if we contrast our comparative unanimity of sentiment without the restraint of external authority with the schisms that rend and disturb the peace of our sister profession—the Church—in spite of rigid creeds and formularies, we shall recognise the wisdom of the principle of trust reposed in us. Trust on the one side begets an honourable obligation on the other which should be stronger than the strength of any law in its effect upon conduct.

But there is another kind of authority much more dangerous to the independence of generous minds than that of any external law whether mandatory or prohibitive. It is that which attaches to great names and to the profound and often just reverence in which the opinion of those who own them are held. When a man distinguished by a long and honourable course of public and private professional life enunciates a dogma, especially if it be with regard to a subject of which he is admittedly a master and if he has advanced the boundaries of medicine and cleared away some of its obscurities, it is apt to be considered as conclusive, not only for the time in which it is uttered, but for all time, and thus the human mind may be trammelled and its advance retarded by appeals to one of its most attractive qualities. Yet the probability is very great, and more and more so in proportion to the appearance of finality that seems to attach to the dogma, that it will turn out to be untrue as time advances. Medicine may not be, and probably never will be, in the strict sense of the term an exact science, yet it so appropriates and makes part of itself the discoveries of many sciences that it must constantly be advancing with them. Under such circumstances dogma is out of place, the seemingly settled truth of to-day not infrequently requiring modification to-morrow in the light shed by some new research. Stokes was such a man as I have pictured, and in 1854 he wrote: "The treatment of fever is reduced to a formula. We cannot cure fever. No man ever cured fever—it will cure itself. If you keep the patient alive till the 14th, the 18th, or the 21st day he will recover." Commenting on these words in an inaugural address, given as President of the Liverpool Medical Institution in 1889, I remarked that "two of these sentences are commonly quoted to-day as axiomatic and as determining the question for all time. 'No man ever cured fever.' Probably not. Certainly not if you like, but no man ever knew what fever was, and until he does know he cannot be expected to be able to apply a rational cure. This knowledge will however be certainly attained, and when it is attained the cure will not remain long unknown." So much for the comment written in 1889. Stokes's statement, which certainly seemed justified by all the facts known at the time when it was made and which would have seemed almost equally so by the knowledge of 1889, is as certainly not justified now, owing to important facts discovered within the past few years. Yet it was frequently brought forward within those years in order to prove that these later supposed facts could not be facts. To-day the knowledge has been obtained. Some kinds of fever are being cured, and in most men's minds there is a confident expectation that before long the remainder will be proved to to be curable.

And that the spirit which would impose strict limitations, beyond which advance shall not be made, is still alive and active we have many proofs. Thus it was but a few months ago that there appeared in the *Gazette Hebdomadaire* a brilliantly written article proving the great danger, if not the impossibility of attempting to cure Pott's curvature of the spine by the method of sudden reduction. The hand of the writer was evidently that of a master. The illustrations were well drawn, and one saw with horror the huge gaping space between the contiguous vertebræ after they had been experimentally fractured in the anatomical laboratory and asked, with the author, by what known reparative process such a space could be filled up. There was so strong an antecedent probability in his proposition, and it was enforced by so much that read like sound reasoning, that, justified by these considerations and by a recollection of the surgical principles early inculcated into my mind by one of the acknowledged masters of this branch of his art—a gentleman whose name I rejoice to see is still on the consulting staff—and fortified by the confidence that always arises from a mere theoretical acquaintance with a subject which can only be thoroughly known by practice, it is not unlikely that I might have felt myself competent to demonstrate to any antagonist the impossibility of successfully performing the operation with as much clearness as Dr. Lardner is said many years ago to have demonstrated on economical and other grounds the impossibility of establishing a remunerative ocean steam navigation. Just eight weeks after the publication of the article I heard with very great surprise and interest that a distinguished surgical colleague of mine intended, in conjunction with a gentleman attached to a school of medicine not far removed from the one in which we are now assembled, suddenly to reduce, after the manner of Calot, the curvature in a number of cases that he had collected for the purpose. The interest of the proceeding determined me to be present to witness this most recent and most daring disregard of an authority rendered venerable by centuries of obedience, and it was with feelings of excitement difficult to suppress that I saw the deformity instantly reduced in five cases in succession, while the tension became positively painful when in one instance the spine gave way under the force applied to it with a crack that resounded all over the theatre, causing those who were present to look at each other with anxious faces indicative of their fears of the immediate effects of so much violence. I asked, and easily obtained, permission closely to examine every case as often as I pleased. The number soon rose from five to many times five, and the first question asked with reference to every one was, What was the amount of the paralysis that was said to be inevitable? The answer was always the same. The inevitable had somehow been avoided; paralysis was uniformly absent. Was there fever? No. But surely, it will be asked, there must have been pain? Yes, there certainly was pain, for I followed many from the operating table, watched them as they emerged from the influence of the anæsthetics and heard their cries. Yet the pain was but evanescent, for on the following day the little patients were smiling and contented, while in all cases, and a late one was aged twenty-two years, the spines were straight and have remained straight ever since. To all the objections henceforward raised against this method, as against so much else, we may reply in the spirit of Pascal's words concerning the treatment of Galileo, "It is in vain that you have procured against Galileo a decree from Rome condemning the opinion of the earth's motion. Assuredly that will never prove it to be at rest, and if we have unerring observations proving that it turns round not all mankind together can keep it from turning and themselves from turning with it."

To authority of another and more insidious kind, which is threatening to weaken the vigour of our profession and which, therefore, has to be watched and if necessary opposed, I will ask your attention. Owing to the many-sidedness of medicine and that rapid expansion of which I spoke at the commencement of this address it is quite impossible for any one man accurately to acquaint himself, even mentally, with all its parts, and equally so for him to attempt to practise them all, and hence specialisation becomes more or less a necessity. But there is a good and a bad specialism. Its tendency just now is to run into ludicrous excess and to

Digitized by Google

infect the public mind with the injurious belief that the human body is composed of a great many minute and independent parts and that he alone can speak with authority concerning any one of these parts who has devoted himself wholly to the consideration of it to the exclusion of all the rest. The departmental habit of mind is always a narrowing one, yet it is one which these ridiculous extremes tend directly to foster. They impair the power of forming a broad and comprehensive conception of man as a whole, whose organs are mutually interdependent, and convert those who run into them into mere prying supervisors of some single organ, or even of some small portion of a single organ. As an illustration of the latest phase of this cutting up process I may mention the work known as "Twentieth Century Practice," now in course of publication. It will consist of twenty volumes, each of some 700 or 750 large octavo pages. Let us take only one portion of the human organism on the whole of which good, sound, common-sense books well worthy of careful study have been written by general physicians, but which in this system is sub-divided into many minute parts and each sub-division handed over to a separate "eminent authority." It does not matter which portion is selected, for the same principle is applied to all alike. Suppose we fix on the respiratory organs. Beginning, then, with the nose—considered, however, in its strictly medical aspect only—we find it handed over to the care of an "eminent authority" in London, but lest he should be weighted with a burden that might prove intolerable to him, the adjacent naso-pharynx, pharynx, and tonsils have to be considered by another in France, while a third, this time in North America, takes charge of the larynx; but the trachea and bronchi being too much for any one man, are consigned, the first to one eminent Scotchman and the second to another; the lungs, but only on the understanding that nothing is to be said of influenza, are confided to a South American; while the last department, that of the accessory sinuses, falls to New York; and a fine comprehensive idea of man as a whole—as one who is "fearfully and wonderfully made," to use the grand but simple language of the Hebrew psalmist—will any student possess who should happen to live long enough to acquaint himself with all the different views of all the different eminent authorities on the disorders of all the different minute sub-divisions of all the organs that go to make up a man as they are set forth in a system like this. The assumption seems to be that by this minute sub-division of labour, between us, and bit by bit, we can get to the very heart of things and solve all the mysteries of life and disease.

It is difficult to give examples of the harm that may be done by the departmental view of man when carried fully out into practice without running the risk of reflecting on persons, which it is very far from my desire to do. It is the system that is bad, while some of those who almost without thought are giving support to it are among the most honourable of men. The injudicious devotee to a specialty—for please remember that it is of him, and him only, that I am speaking, and not, as I shall explain further on, of the legitimate and useful specialist—has usually a very large amount of enthusiasm and a very moderate amount of judgment. He devotes his whole mind and thought to a small section, or not unusually to a particular method of treating the disorders of a small section of the body, and can see nothing and think of nothing except in relation to it. He often sees what nobody else can see and hears what nobody else can hear, and, moreover, not unfrequently takes his patient into a close and confidential co-partnery with himself in his special knowledge and methods, and thereby does him more harm than all his efforts, however well intended, can do him good, for what is essential in most cases is to divert the attention from, and not to concentrate it on, the diseased organ, if it really is diseased, and not to give it the appearance of being diseased if it is not. It is of comparatively little importance which organ of the body is taken by way of illustration. The strongest-minded man among us would quickly have his strength converted into weakness if daily and hourly by the very method which was to cure him of some real or supposed ailment he was made to think of it instead of everything but it. Take the heart. I have in my mind a refined, scholarly, sensitive man, who had the double misfortune for one constituted as he was to inherit large wealth and to adopt a profession which seems to be thought inconsistent with the enjoyment of many innocent indoor and outdoor sports. I never saw him but once, and that after he had been led to place himself under the care—so I learned from his medical adviser—of an eminent authority who had a special system for converting diseased hearts into healthy ones, and he (the patient) showed me with an intense but wholly misplaced interest large charts on which the outline of his heart had been mapped out for him before he began the treatment, during its continuance, and after it was ended. These charts had been given to him for his information, guidance, and encouragement, and as well a little book accurately indicating—the directions being illustrated by drawings—what was to be done each day and each portion of each day. The result was what might have been anticipated by any man of common sense and broad general ideas of a nervous man's constitution. Though the condition of the heart grew better and better—the charts were declared to prove that, and the patient implicitly believed it—the general condition grew worse and worse. The heart certainly was not diseased when I saw him. If, therefore, it ever had been this system may possibly be accredited with the change. But what is the advantage of curing a man's heart if by the very method of cure you make him a more pitiable valetudinarian than he was before it was tried or than nature ever designed him to be? The patient does not know, he cannot know, and he ought not to know, anything about the area of dulness that can be mapped out by skilled fingers, and a chart of which is useful enough when made and kept for the practitioner's own information or for that of another; and to make him believe that he does know it is to do him harm; and if this kind of treatment is suggested in good faith, the faith must be much stronger that the judgment. You devote years of your life to acquiring the knowledge that will enable you to determine whether a heart is healthy or unhealthy, dilated or not dilated. At the end of your first year you will be much puzzled in your efforts to clear up the point, and is it to be believed that the method of resolving the doubt can be intelligibly communicated to a patient, who has had none of your preliminary training, in a few minutes? Or take another organ. Not long ago a stranger—a lady—consulted me who in a similar way had been made to believe by an eminent authority that she knew what in no proper sense she ever could know, for the knowledge at the very best could be to her but a knowledge of words and not of things, many minute details concerning an ailment from, instead of to, which her mind might advantageously have been directed. She also presented a chart on which everything had been put down in the most exact—the most scientifically exact, as it is called—and detailed manner. If the facts, as set forth, had been communicated by one medical man who happened to know more of the subject to another who happened to know less, it could not possibly have done any harm, even if it did no good. But it is quite another matter when there is given to a nervous person for permanent reference a formal sheet, on which she is informed that the disease from which she is suffering is "uric acid diathesis from sluggish liver," and that the 800 cubic centimetres of an important liquid excretion examined had a specific gravity of 1026, an amber colour and reaction; 3·306 (so precise was it) percentage of urea, increased uric acid, normal chlorides and alkaline sulphates, but slight excess of aromatic sulphates; that phosphates were in excess; that no hæmatin or urobilin was present; that indican was increased, but that happily bile pigment and bile acids were absent; that there was a slight amount of mucus, but neither sugar, acetone, aceto-acetic acid, hippuric acid, nor oxalic acid; that the sediment was slight, but that, slight though it was, it contained "numerous quadriurates and some uric acid crystals, epithelial cells, and a few casts." It was evidently with no small feeling of alarm, and yet at the same time with something of conscious pride at being the subject of so many very extraordinary things, that she favoured me with a sight of the document, and I am not sure that my efforts to reassure her by telling her that the whole thing was of no serious importance may not have been more successful in hurting her pride than in diverting her attention from what was injuring her by a constant contemplation of it. It ought, perhaps, to be added that the full name of the eminent authority and his official residence conspicuously and consistently ended the statement. These are examples of a kind of authority which I venture to think is bad—at least, in the mode in which it is exercised—which is increasing, and which ought to be checked. But how can we help to check the illegitimate and unwise specialism while availing ourselves of that which is legitimate and wise? I will tell you. By the assiduous cultivation of a robust but modest independence of mind founded on

Digitized by Google

an accurate knowledge of facts actually and often observed. This is something very different from conceit, which in the practising as much as in the non-practising student—for every one of us must all our life long continue to be a student—is insufferable. It should be an encouragement even to the youngest to know that it was on cases accurately observed and recorded during his hospital student days that Laennec founded that great work that revolutionised medicine and made for himself an enduring fame as a benefactor of his profession and his race. If I selected any portion of this syllabus as being in my judgment specially valuable where all is so valuable it would be that which says that great importance is attached to individual teaching at the bedside and in the special departments. This is the kind of teaching which of all others is most strongly and permanently stamped in upon the mind, and if it were attended to as thoroughly as it should be medical men would enter on the work of their lives with a quiet and assured confidence in no other way attainable—a confidence in themselves which would make them unassailable by the criticism of those whose practice may be more special than their own. It is fear arising from consciousness of ignorance that brings mental subserviency and makes a man readily defer to the dogmatically asserted statement of others, and it is not fair to ourselves or our profession willingly to consent to see with another man's eyes what with a little extra trouble we can learn very well how to see with our own.

> "Segnius irritant animos demissa per aurem,
> Quam quæ sunt oculis subjecta fidelibus ....."

says Horace in his "Ars Poetica," and this is a maxim that should be imprinted deeply on the mind of every medical student.

Are we all to know everything then? No. As I have already said, there must be specialists in a profession so many-sided as ours. I have mentioned what I venture to think some of the injurious forms of this. I will now narrate an incident which struck me very forcibly at the time of its occurrence as showing, not only the necessity of specialism, but as defining to a certain extent its just limits. It happened a long time ago, during one of the years of my presidency of the Liverpool Medical Institution, that a small pedunculated tumour was shown which had been removed from one of the vocal cords of a gentleman who had been hoarse, and at times completely voiceless, for years. He had consulted many medical men without the least advantage until, coming at length under the notice of a general surgeon, he was for the first time carefully examined by the laryngoscope and the cause of all his trouble recognised. But what did this gentleman do? Remember he was, and is, possessed not only of great skill as an operator, acquired in the practice of one or the largest provincial hospitals, but also of sound surgical judgment. What did he do then? Why, he told the patient with that assured confidence which, as I say, can only come of a knowledge acquired by careful observation, conducted by the only means that can make the observation careful, exactly what was the matter with him, but he did not attempt to relieve him. He felt that to do this required a manipulative dexterity in the use of delicate instruments which could only be acquired by long and special practice, and he sent him to a gentleman who had acquired this qualification, and who by means of it soon effected a cure. Now what I venture to say is that it would have been as wrong for the general surgeon to have tried to do the special work as it would have been for him not to ascertain for himself what the special work was that had to be done. And what I further venture to say to you, gentlemen, is that if with the admirable facilities afforded to you by this and the neighbouring institution for acquiring an accurate knowledge of the use of such instruments as the ophthalmoscope and the laryngoscope for the purposes of observation, and of telling your patients what is or is not the matter with them, so far as those instruments can enable you to do so (and I only use them as illustrations), and whither they may perhaps go to obtain relief, you will be no more true to yourselves or your profession than you will be if with this increased power of accurate observation you confuse in your minds and consciences the power to observe well with the ability to operate well, which are two entirely different things, and things which an honest mind will always keep distinct from each other.

But can there possibly be time for the acquisition of all this knowledge? I admit that a medical curriculum looks very formidable when viewed as a whole and that you could not possibly conquer it if you had to attack it all at once; but if ever you should be inclined to despond at the magnitude of the work to be accomplished think of what the dial-plate said to the discontented pendulum when one morning it suddenly stopped swinging through fright at the work to be got through in the course of a year. "It is not of six strokes that I complain," said the pendulum, after finding on trial that it could manage these without fatigue, "nor of sixty, but of millions." "Very good," replied the dial plate, "but recollect that although you may think of a million strokes in an instant you are required to execute but one, and that, however often you may hereafter have to swing, a moment will always be given to swing in." If you carry out the syllabus on this principle and in this spirit there will be—indeed, there must be—not only plenty of time for this work, but plenty also for much else about which, if medicine through you is to exercise that authoritative influence on the national life which is so essential for its progress, it is necessary that you should form sound judgments based upon sound knowledge.

Take the great subject of our recreations, on which you will be consulted every day of your lives, and which is becoming daily of greater importance now that shorter hours of labour are everywhere becoming more general. On no subject ought medical opinion to be more clear and precise than on this. If the brain is to work healthfully it must have its due periods of diversion and of rest, and a portion of this diversion cannot better be obtained than by the pursuit of those magnificent outdoor sports which happily are the glory as they are the strength of our race. This noble passion for cricket, boating, cycling, golfing, football, hunting across country, shooting over moors, for everything, indeed, that tends to foster hardihood, muscular endurance, a fine spirit of fair play and justice, as well as health, should be encouraged and never repressed by us who are best qualified to judge of its effects. Do not lightly tell a mother on some petty technical ground and with an air of authority that cycling will not be good for her daughter. Her indulging in this fine exercise may make all the difference between her becoming a Katherina or an Imogen. But the best way to prove the value of your doctrines to the public is to practise them yourselves. I do not believe that any man can thoroughly and healthfully master his curriculum without indulging largely in some form of severe physical exercise. Recreation—re-creation—so necessary for each one of us if we are to do our work well, is obtainable no doubt in many different ways, but in few perhaps better than such as those afforded by the students' club, with its branches of cricket, football, tennis, and I should hope in the near future, if not at present, cycling, swimming, and other forms of athletic exercise—a department of college life of inestimable advantage, and one in which you have ample means of obtaining the relief which you should require if your work within wards and class-rooms is done as it ought to be. An experiment of great value, as it seems to me, and one to which I often refer, was performed by Mr. Charles Paget, formerly M.P. for Nottingham, in the village school on his estate at Ruddington, and the principle underlying which is equally applicable to a medical school in London or anywhere else. He was not satisfied with the general progress made by the boys and provided for them therefore a large garden. The school was then divided into two sections, one of which was kept to the ordinary school work for the ordinary hours, the other for half of these hours only, the rest of the school time being devoted to work in the garden. At the end of the term, the half-term, or gardening boys, had excelled the others in every respect—in conduct, in diligence, and in the results of study. In these times of brain-pressure such a fact as that may well be remembered by all of us in relation both to our own needs and those of the public.

This perhaps is the most appropriate place briefly to mention one other matter of general importance as affecting the medical man's and (through the individual medical man) the medical profession's influence upon the society of his time. He of all others ought to be a man of general culture. Everywhere throughout the kingdom he is being asked to take part in the public life of the place in which he resides, and as a member of urban or district council, board of guardians, bench of magistrates, school board, or otherwise, has opportunities of impressing that life with his own ideas. Yet the more technical portion of his reading is of such a character as to shut it out, and to shut him out

Digitized by Google

also, from general society if he can talk and think of nothing but it. In one of two addresses given some twenty years ago to the students of Cheshunt College by the late Dean Stanley he expressed the hope that Sir Walter Scott's novels were among the best part of their theological reading. What has always struck me as a misfortune is the readiness with which medical men drop all that earlier classical knowledge on which as a foundation their more technical instruction is reared. Yet it would be very easy to keep it up, though difficult to re-acquire it when lost. Every medical student has, for example, to make himself acquainted with at least one book of some Latin author; and every medical man has to write prescriptions into which Latin enters. An hour, or perhaps half-an-hour, a week would be quite enough to keep up his acquaintance with the first, which, if it were done, besides being valuable to the mind generally, would make the particular exhibitions of defective culture in the latter less remarkable than they too frequently are at present. It certainly is not advantageous to us as a profession, and not likely to promote our influence on the educated people of our times, when such words as these which I remember to have read in a review written nearly forty years ago on the best-known and most quoted Latin poet—words which are certainly as true now as then—are thought applicable to us. "The country gentleman, the clergyman, sometimes even the lawyer and the doctor, ... all draw from the same well instances and illustrations." *Even* the lawyer, and, last of all, *even* the doctor! I am not pleading for pedantry or for a pretence of a full and critical acquaintance with ancient classical authors, which latter it is impossible that we can possess, but merely for such a continuance of, and possibly advance on, our school or college acquirements as shall not make us feel on a lower level of education than that occupied by the reviewer's country gentleman. But whether this kind of learning is kept up or not other kinds must be, for consciously or unconsciously to ourselves as a nation, but surely and steadily, changes are everywhere being wrought in the great forces of civilisation and commerce which, if they are to issue in good rather than evil, should be clearly recognised by medical men and made the subjects of their calm, deliberate, and intelligent judgments. I can only briefly allude to some of these. It will be for you to reflect on them.

The strong, swift, and ever-increasing set of the current of human life from the country to the great towns is one of them. It is idle to lament, and still more to try to prevent this. But what is not idle is clearly to apprehend the causes which in all past times made the aggregation of vast numbers of human beings into limited areas injurious to health, to attack and overcome these causes, and thus to make city life not only physically healthy, but what it is always capable of being—intellectually and morally the noblest kind of life. The work done in this direction in recent years is enormous, but the problems which remain are great, and are such as medical men alone can effectually solve. And it is no small earnest of their ultimate success that this vast city, unexampled in all time for the extent of its population, has been made under the enlightened and judicious counsels of such men as Sir John Simon, Sir Richard Thorne Thorne, the late Sir George Buchanan, and others, not only one of the healthiest cities of the world, but far healthier even than many rural districts. I will venture to quote one question and answer from the first report of the Health of Towns Commission. Dr. Neill Arnot was the witness. "From what you have seen with respect to the state of the atmosphere in buildings generally, do not you consider that it would be a matter of great importance, not only for medical men, but also for architects and engineers, that the subject"—i.e., of ventilation—"should be enforced as a branch of education among those professional classes?" "I do," was the reply. "I think acquaintance with it almost as important to the utility of a medical man as acquaintance with anatomy."

Another of the great social questions which presses for solution, and in which the voice of medicine should be clearly and authoritatively heard, is the *rôle* which alcohol plays in the individual, social, and national life of our time. I am not going to take an unfair advantage of my position here to preach on the utility of total abstinence. But I should be failing in my duty if I did not urge upon you the necessity of a careful and independent consideration of this subject, not guided alone by the small experiments of the laboratory, but by those larger experiments that are being performed for us in every city and village of our land, and the results of which can be witnessed in ruined health in thousands of wrecked and wretched homes, in gaols, in workhouses, in asylums, and in hospitals. Those facts and figures on a large scale, which, in his appendix to the Registrar-General's Thirty-ninth Annual Report, the late Dr. Farr regarded as necessary for determining this question, have, since the publication of that report, and probably in consequence of it, been supplied, and should be carefully weighed by every medical man.

Although I have taxed your patience very long I must for a few minutes before concluding allude to one other department in which demands on our faith and even on our credulity of a very exacting character have been made by those who, owing to the special nature of their studies, claim to speak with the voice of authority. I allude to that dark region that is intimately but mysteriously associated with the operations of mind. Here especially, while acknowledging with thankfulness whatever there is of real discovery, we have need to guard ourselves against a too slavish submission. There are certain fundamental principles on which human society is established and which cannot be disturbed without seriously disturbing it. Such are the great moral intuitions, as we have been content to consider them. We know that we are possessed of them as certainly as we know anything, and more certainly than we know most things, but that is all. If the cerebral pathologist or physiologist could afford the slightest real clue to the solution of the most intricate of all problems, the relation between the brain and thought, the genesis of will and of the idea of responsibility, we should thankfully accept it. But when, instead of doing this, he informs us that these supposed moral intuitions are, after all, nothing but delusions, that he has investigated the matter and discovered that what, for example, we in our ignorance suppose to be a free exercise of will is not so, but that "by a strange phenomenon of which *we are incessantly the dupes* it comes to light in the *form* of spontaneity in our ideas, our work, our acts," we are entitled to ask him for proofs, and to demand that the proofs shall be rigid and exact and not a pretentious display of real ignorance dressed in high-sounding but meaningless phrases; and especially are we entitled to demand this when by virtue of his special knowledge he assumes an air of superiority over all those who have gone before him. Let me for a moment or two ask your opinion on a few of the alleged explanations of the inexplicable that have been given to us by some of our self-styled philosophic physicians—for, gentlemen, neither you nor I have any right weakly to renounce our judgment in matters such as these. One of them complains that "the controversies of philosophers and metaphysicians which have been taking place from time immemorial have succeeded in arriving but at one thing—the expression in sonorous language of their ignorance, more or less complete, of the fundamental characters of psychical life," and thus raises in our minds the expectation of a lucid and simple exposition about which there can be no doubt. You must judge. To start with, we are told that there are certain fundamental properties of nervous tissue, among which are organic phosphorescence and automatism. Everything then becomes plain. Does it puzzle you to understand by what process sensibility can become a property of matter? It is only a proof that you have not read M. Luys on the Brain and its Functions, for it comes about in this wise. "The simple physical impression produced by the external world is transformed as it becomes incorporated with the organic tissues into nervous vibrations, and these nervous vibrations passing through successive agglomerations of cells undergo the action of the different media through which they pass until they arrive, transformed and purified, in the plexuses of the cortical substances, which are set in motion impressed and vivified by them alone"; and again, "The connexions between the peripheral plexuses and those of the sensorium are so intimate that so soon as an impression has been produced in the former their partner cerebral regions immediately enter into unison with them. There is a nervous condition of similar pitch which harmonises one part with another, and whenever the primordial impression has been sufficiently intense and sufficiently prolonged, whenever there has been an effective participation of the nervous plexuses laid under contribution, the partner plexuses of the cerebrum sympathetically associate in their excitation and enter upon a concordant period of erethism. The incident excitation arrives, then, in the plexuses of the cortical substance purified and animalised by the peculiar

metabolic action of the nervous plexuses in the womb of which it is incarnated, and then transforming itself into a psychic excitation it develops the latent energies proper to the cerebral cells, imprints itself upon them, and perpetuates itself in them in the form of persistent vibrations like a phosphoric gleam of the external world."

Very much in the same spirit writes another distinguished authority in the same realm of medicine. Like Dr. Luys, Dr. Maudsley is very severe on the "philosophers of the study" who "indulge in vagueness of thought and expression, and seem to be unable to get clear and exact notions of psychological facts in their mental relations." He resolves, therefore, so he tells us, "to leave the barren heights of speculation for the plains on which men live and move and have their being." Clearness and exactitude of thought and expression are certainly most desirable ends. Whether your own notions as to sensations are more clear and exact than they were before, when you find them spoken of as "representing the source of multitudes of activities that are going on below the threshold of consciousness, and which, albeit unperceived and unfelt, immediately vibrate subtilely in the most intimate and intricate interactions of organic depths and in the result deeply affect the tone of consciousness," you must judge. Or perhaps, if not absolutely enlightened by this, you will become so after reading a little further on that there are "two leading facts, and for us ultimate facts, which it behoves us to apprehend and fix firmly in mind—first, that there has been what we may call a *nisus* of nature, and secondly, that successive transpeciations of matter have been events of it. Continuity of nature certainly, but as certainly not of kind in nature, for the continuity is of different kinds, therefore in some sort a discontinuity, a new springing up from the bases of the old kind—not continuity by homogeneous but by heterogeneous generation." You will no doubt recognise from the unexampled lucidity of thought and exactitude of expression displayed in these passages the advantage of leaving the barren heights of speculation in which men expressed in sonorous language their ignorance more or less complete of the fundamental characters of psychical life; and coming down modestly to the plains where authoritative guides can address us in language which all can understand. And you will probably not be surprised to be informed that "it is the superaddition of consciousness"—and nothing more than that—"to definite susceptibility to impressions, and definite reaction thereto, which are common properties of all organic matter, that makes them sensation and effort." It is all so very simple. One would imagine that this superaddition of consciousness to various kinds of organic matter imparting to it sensation and effort were taking place under our eyes every day of our lives, so offhand is the manner in which it is thus casually alluded to. Whereas this is the very problem of problems, the solution of which, whether attempted on the mountain or the plain, by means of the microscope or without it, eludes us, as it has always done, and is as far off now as ever. And probably our deference to authority in this branch of our studies will be considerably shaken when we listen to the final results as given by the two authors themselves, each in his own language. Thus Dr. Maudsley assures us with reference to every possible human action that the doer of it "certainly could not have done otherwise than as he did on that occasion, but he is not, therefore, fate-bound to do the same on another occasion"; while, according to Dr. Luys, besides being dupes of a supposed moral freedom which we do not possess, "we see, then, to sum up what precedes, that the processes which produce voluntary motion pass in their evolution through phases inverse to those of the processes of sensibility. While these latter, as they approach to the central regions of the sensorium, are purified and made perfect, being more and more intellectualised by the metabolic action of the different nervous media through which they are propagated, the former, on the contrary, conceived as psychical vibrations at the moment of their genesis, amplify and are materialised more and more as they descend from superior regions. They become complicated by the addition of adventitious elements which reinforce them as they progress ..... and thus become in the last term of their evolution a true synthesis of agglomerated organic elements, which resume in themselves the vital forces of the system through which they have been developed." "Conceived under this simple formula," says the author—"simple," mind! of all other terms applicable to such a formula,—"conceived under this simple formula, the processes which produce voluntary motion present the fascinating picture we constantly see presented to us in the working of steam-engines."

Very fascinating, truly! Very lofty and ennobling! How different is the spirit displayed in writing such as this from that of one whose name can never be mentioned here without a feeling of respect and pride. Huxley craved for truth in these, as in other, great questions, but he hated shams and pretences too intensely to deceive himself or others into the belief that he had attained to it so long as there was room to doubt; and in all the great controversies of his, which are indeed the controversies of our time, was willing to admit the limitations of human knowledge. When it was a question of the origin of life, and assertions were dogmatically made as to its alleged outcome from not living matter, there was no ambiguity or want of clearness in his utterance. "The fact is," he wrote, "that at the present moment there is not a shadow of trustworthy direct evidence that abiogenesis does take place, or has taken place within the period during which the existence of life on the globe is recorded"; and in another place "the present state of our knowledge furnishes us with no link between the living and the not living"; when it was one of the relations between matter and thought the same fair, candid, and cautious spirit manifested itself. "Matter may be regarded as a form of thought; thought may be regarded as a property of matter; each statement has a certain relative truth."

How different is this from that proud and self-sufficient philosophy which pretends to explain all things, pretends to a knowledge which it does not possess. Mystery, reverence, awe are all to disappear before the penetrating gaze of these cerebral philosophers. The heights of man's noblest aspirations, the depths of his deepest despair, his spiritual cravings, his consciousness of moral freedom, are all to be explained on purely physical theories and by purely physical processes. That he is a being who has within himself anything whatever that cannot be seen by the modern microscopist, or analysed by the advanced chemistry of the latter end of the nineteenth century, or searched through and through by Roentgen rays, can hardly be credited by the self-sufficient philosophy which is doing its utmost to tyrannise over us to-day. Actions and inter-actions between stimuli and nerve-cells, which the subjects of them can no more control than they can the growth of their hair or nails, must in some way be made to account for remorse, anger, will, and every other quality of mind; and, this being so, they are made to account for them—at least, to the satisfaction of the philosophers themselves, if of nobody else. Conviction, conscience, devotion to the death in the cause of truth, and many another noble characteristic of our species which no mere philosophy of the scalpel and test-tube can comprehend, have to be carefully considered as important facts of human nature by medical men. Gentlemen, on such questions as these also, on a right or wrong view of which the happiness of mankind so much depends, we must preserve a strong if unobtrusive independence of mind. To use the words of Bishop Butler, "Let reason be kept to"; and if proofs can be given that the undying beliefs in the truth of these great moral intuitions are ill-founded, then let them, "in the name of God, be given up," but let us not be content to be cheated out of them by a mere trick of high-sounding but meaningless phrases.

The schools of medicine are probably at this moment the most stimulating schools of thought throughout the whole world. That "sacred torpidity" which is said still to permeate at least one of the older seats of learning, and to "dishearten early" all but its boldest intellects, is unknown and unfelt here. The great problems of life, disease, and death are too intense and too close at hand to admit of lethargy. But in the stimulation there may be danger. Speculation is apt to run riot. In attempting, then, the solution of these problems, if and when they are soluble, do not in a spirit of slavish submission bow down to authority. Do not, on the other hand, in a spirit of recklessness and to show the world how independent you are, needlessly run counter to it because it is authority. But with pure and honest hearts, conscious of a manly integrity, and with a noble but quiet determination to fulfil to the utmost those sacred duties which it has pleased Almighty God in His Providence to entrust you with, "prove all things and hold fast that which is good."

An Introductory Address

ON

THE MEDICAL STUDENT: HIS WORK AND ITS OBJECT.

Delivered to the Students of the Medical Faculty of University College, London, on Oct. 4th, 1897.

BY RAYMOND JOHNSON, M.B., B.S. LOND., F.R.C.S. ENG.

GENTLEMEN,—We are assembled here to-day to inaugurate the seventieth winter session of the Medical Faculty of this College, and those of you who are beginning your studies and those who are continuing or concluding them are invited to meet together and listen to an introductory address. From time immemorial it has been the custom to surround the admission of students to the profession of medicine with some kind of ceremony. Thus we are told that in the earliest Sanscrit writings the function is described as of a most imposing character. The gods were first propitiated by numerous offerings and then the students were treated to an excellent introductory lecture in which, amongst other things, the teacher counselled them "to be chaste and temperate, to speak the truth, to obey him in all things, and to wear a beard." And in passing it may be remarked that this matter of the beard seems ever to have been under consideration, and by the middle of the sixteenth century it was decided that no apprentice of the Barber-Surgeons Company should wear a beard of more than fifteen days' growth, the penalty being that the unshaven apprentice should forfeit his apprenticeship and that his master should pay a fine of 6*s* 8*d*. Doubtless this regulation was framed with an eye to business, for since the professions of barbery and surgery have been divorced from each other, the medical student has been allowed to follow his own tastes entirely in the clothing of his chin.

It seems but natural that we should begin our year's work by a general meeting together before we start off upon our different duties and doubtless the delivery of an introductory address is a very business-like commencement. Personally, however, I had wished that on this occasion the well-worn custom had been honoured in the breach rather than in the observance and that, having heard the Dean's report and the announcement of the prizes, you, gentlemen, might be free to spend the remainder of the meeting in some more congenial manner than in gathering the dry crumbs which are the best that I can offer you. You are familiar with the words:

> "Some are born great,
> Some achieve greatness,
> And some have greatness thrust upon them."

If my position here to-day is any evidence of greatness I can assure you it has been thrust upon me. And yet, gentlemen, my first and chief duty is a very easy and a very pleasant one—to wish those of you who are here for the first time to-day a very hearty welcome to University College. May the years you spend within these walls be the happy ones they have been to hundreds before you. May the friendships you make grow firmer with advancing time and be something much deeper than mere acquaintances. May you never have reason to regret your choice of a medical school, but may University College become in the highest sense your Alma Mater to whom in future years, wherever your lines may be fallen, you may look with gratitude and respect—I would venture to say with love. Gentlemen, the profession which you have selected for your life's work will call for the exercise of all your energy if you wish for any success. In no other circumstances could you find a wider field for your labours, for I may with confidence assume that each one of you desires to become a widely-informed scientific worker, and something much higher than a mere "medicine man." To none more fully than to those who are engaged in the study of medicine do the words of Alexander Pope apply:

> "The proper study of mankind is man."

We are concerned with man. Man is the material upon which we are called to exercise our craft, and therefore there is nothing concerning mankind at large which a medical man will not be the better for knowing. A great physician has said that each case which comes before us should be considered as "the disease + the person." The "disease" element is provided for in the medical curriculum, the "person" element can only be fathomed by him who from experience has learned to make a rapid and accurate estimate of the man with whom he has to deal. And thus it is that a medical man should be in the highest sense "a man of the world." Let me urge you, therefore not to allow the keen interest which you cannot fail to have in your medical studies to prevent you widening your general knowledge in every possible direction. Keep up your general reading, take a lively interest in all that is going on in the world, and never lose an opportunity of adding to your fund of general information. In your everyday work you will be brought into contact with every conceivable variety of individual, and the more thoroughly you can put yourself into the position of your patient the more accurately will you be able to estimate the personal element of which I have been speaking.

Be sure of this, also, that your patients will expect of you much knowledge which can hardly be called medical. The family medical man is consulted about all kinds of matters which have but a very indirect bearing on his profession, questions which only a sound common-sense and a rich fund of general information can enable him to answer. He is a witness of many plays on the stage of life, and if he would enter into the spirit of the actors he must be a man of "many parts." Each one from "the infant mewling and puking in the nurse's arms" onward to the "lean and slippered pantaloon" and the weary player in the "last scene of all" will look to the doctor for sympathetic interest and will expect to find in him an intimate acquaintance with the part he plays.

These remarks may seem to you somewhat premature at this stage of your proceedings, but it is just when the student's mind first becomes engrossed with the many subjects of our crowded curriculum that there is the greatest danger of general knowledge and culture being neglected; and although it is perfectly true that an earnest worker must find his greatest happiness in his work, it is none the less true that much additional happiness and healthy relaxation can be obtained from outside interests. A hard-worked man without a hobby is like a high-pressure boiler without a safety-valve, likely to burst from overstrain at any moment. Some men are so engrossed with their work that they cannot even enjoy a holiday, and should they in due course be able to retire from active practice, instead of spending their declining years in well-earned leisure, they break up and die, literally from want of something to do. The course of study which you begin to-day resolves itself into two great periods—first, that in which you are concerned with the structure and functions of the healthy human body, together with the study of such sciences as may help to elucidate them, and, secondly, the period in which you will study disease in all its aspects. The importance of thoroughness and method in your earlier studies cannot be exaggerated, for they possess a double value. Not only are they obviously indispensable as a preliminary to the strictly medical part of the course, but they afford an invaluable training of the powers of observation and a means of acquiring a scientific habit of mind. They have, therefore, both a strictly technical and a general educational value. For this reason such subjects as anatomy and physiology demand the most thorough and painstaking study. Frequently the student will find himself confronted with matters in which he fails to see the remotest possibility of any practical application. Not the less on this account must he endeavour to master them and who indeed shall venture to pick out the smallest fact in anatomy or physiology which is necessarily devoid of all practical importance? The study of chemistry, moreover, is daily becoming of greater importance for the proper understanding of the nature and treatment of disease.

Above all things I would implore you not to neglect your practical work in the dissecting room. A thorough knowledge of anatomy will prove of inestimable value to you and can be obtained only in one way—by actual dissection. You may supplement this by the study of text-books, but anatomy learned by reading only is an empty sham. The student may know in order every branch of every nerve and every artery, and be able to draw the brachial plexus on a blackboard with his eyes shut, and yet altogether fail to recognise even the most important of the structures about which he knows so much when he meets with them in their only

Digitized by Google

right, but to him unfamiliar, place—the body. Who is not familiar with the sorry sight of the would-be anatomist who, armed with a "Pocket Gray" in one coat-tail and a packet of diagrams and mnemonics in prose and verse in the other, is vainly endeavouring, with the additional aid of illustrations and other people's dissections, to cram up in a few short weeks the knowledge which he should gradually have been acquiring by diligent work in the dissecting room? Such a quasi-knowledge of anatomy may, if the student have good luck, secure him the minimum of marks required for a pass at an anatomical examination, but it will disappear as quickly as it was acquired and need not be mourned for, being from the practical point of view absolutely valueless. At the present time a strong plea for individual practical work in anatomy and the other subjects of the earlier part of the curriculum seems to me to be particularly necessary. The medical curriculum is very crowded—possibly over-crowded—and the constant chain of classes and demonstrations which the student is called upon to attend is in danger of seriously curtailing the time devoted to individual study, especially in practical anatomy. Indeed, I fear that we are in risk of unduly multiplying these classes and demonstrations, valuable as they are, if rightly employed.

There is a grievous error into which the medical student is very apt to fall, that of regarding the acquisition of knowledge as necessary merely for the successful passing of his examinations. Examinations are a very necessary evil, for by such means alone is it possible to determine, however imperfectly, that a student has acquired that degree of knowledge which entitles him to receive official permission to practise his profession. Some such guarantee must be forthcoming; the public who place themselves in our hands demand it, and the State, which entrusts important duties to the medical profession, must have some guarantee of fitness. It is disastrous, however, to regard those tests as the final object of study. And yet how often is the mistake made! The result is invariably the same: the student's work becomes paroxysmal, and occasional periods of phenomenal exertion are separated by long intervals of more or less complete quiescence. In these circumstances the one endeavour is to induce the brain to assimilate for the time being the necessary store of facts, which must be so condensed and arranged as shall fit them to be the more readily brought forth again in the time of need. It is a travesty of the name of knowledge to apply it to such a conglomeration. The information thus obtained lacks, amongst other things, all perspective. Each solitary fact stands out of all relations to its surroundings. The "likely" and the "unlikely," the "probable" and the "possible," are all hopelessly jumbled together. Such information cannot be used for practical application, and is too frequently concerned with the extraordinary to the exclusion of the commonplace. One man may be able to rattle off quite faultlessly the course and branches of of all the petrosal nerves, and yet hardly be able to distinguish a kidney from a spleen, whilst yet another can construct a list as long as his arm of the causes of retention of urine, putting dislocation of the femur in the perineum at the top, and adding stricture of the urethra as an afterthought at the bottom. Gentlemen, let me urge you to look to the quality as well as to the quantity of your knowledge, and aim at something higher than the bare minimum with which so many are content. George Herbert's advice is excellent—

> "Pitch thy behaviour low, thy projects high
> So shalt thou humble and magnanimous be,
> Sink not in spirit: who aimeth at the sky
> Shoots higher much than he that means a tree:"

advice which we may more particularly accept because the poet concludes his verse—

> "A grain of glory mixed with humbleness
> Cures both a fever and lethargicness."

Obtain your knowledge at the fountain head and digest it down by your own efforts, so that it may become assimilated and form an integral part of yourselves. Do not crave too much for specially prepared knowledge or you will lose the power of teaching yourselves, and in course of time, according to the law that the supply is determined by the demand, you will convert the teachers into mere cramming machines warranted to force the largest amount of semi-digested intellectual pap into the student in the shortest possible time and with the least possible effort on the part of himself.

Much has been said in introductory addresses and elsewhere both for and against the systematic courses of lectures which will engage a good deal of your time and attention. Some men—I believe the great majority—can obtain a better grasp of a subject by listening for an hour to the expositions of a capable lecturer than by spending a similar period of time in reading the best of text-books. It is proverbially easier to express ideas in speech than to commit them to writing, whilst the individuality of the teacher should be an important help in impressing the facts which he is endeavouring to elucidate. Moreover, a clear lecturer may avoid uncertainty by a degree of repetition which would hardly be pardonable in the pages of a manual, and is able to draw similes and quote instances which would appear trivial if reduced to black and white. But I would say, if a student honestly believes that he can employ his time better than by attending lectures by all means let him do so; he alone is the loser if he has judged wrongly. Let his absence, however, be honestly due to this belief alone and not in the least degree determined by the fact that the hour fixed for these discourses is often 9 o'clock in the morning. I would repeat that for most men attendance at lectures is one of the most useful means of acquiring knowledge. Frequently, however, a most industrious student may altogether lose the chief value of the lecture by a misdirected energy in note-taking. He labours incessantly from beginning to end taking down the words of the lecturer as far as he can verbatim, and possibly spending much of his evenings in making a fair copy. He thus provides himself at infinite trouble with what is practically the unrevised proof of a text-book on the subject. The serious weak point in such a system is that the student gains nothing during the hour of lecture except a certain quantity of written material from which, doubtless, he may gain useful information by subsequent study, but which has lost the personal stamp of the lecturer. Let the most that is attempted during the lecture be to go carefully with the lecturer along the course which he marks out and merely to note down in the shortest manner the main headings of an argument or of the facts under consideration which may be somewhat amplified when the matter is being subsequently studied.

It so happens that in this College a main thoroughfare runs between the medical school and the hospital, an arrangement which serves to impress the maxim—do not meddle with the affairs on the other side of the road until you have finished with those on this. Nothing is gained, but much valuable time is lost, by a student who is occupied with the earlier part of the curriculum resorting to the operating theatre or wards of the hospital. The desire which attracts him there is not much higher than that which induces a crowd to collect at the sight of an ambulance in the street—morbid curiosity. The sights presented to him are but meaningless tragedies unsoftened by the real interest they will possess for him if only he will wait until he comes to study and not merely to gaze upon them. It is, indeed, needless for me to assure you that only by the most steady and persevering application to your work will you be able to master all that is required of you in the first two years of your studentship. Do not let the first burst of energy be a mere flash in the pan, but begin steadily as you mean to go on.

It may be thought by some that the question of a medical student's recreations, which are not provided for in the curriculum, hardly comes within the scope of an introductory address. Surely, it may be urged, a man may be left to make his own plans for his recreations and amusements. Quite so, and yet surely it is highly desirable that in any institution where men are collected together for purposes of study all reasonable facilities should be afforded by the authorities for the different forms of athletic exercises. In this respect the medical schools of London have been well to the front, and it should be the endeavour of the students of this College to see that their school takes its proper place in the cricket and football fields as well as in the more serious fields of learning and research. Thanks to the Union Society, to which every student and teacher should, if possible, belong, we are now in possession of an excellent athletic ground, and thus a long-felt want has been supplied. To every man, whatever his occupation, regular out-door exercise is absolutely necessary if he wishes to remain the possessor of a healthy mind in a healthy body, and it must be remembered that a professional man is dependent upon his own individual efforts and may

Digitized by Google

be compelled to abandon his practice for a degree of ill-health which in many other circumstances would not prevent him remaining at the head of his concerns. It should be his endeavour, therefore, to remain in good working order as long as he can. Whatever form of recreation is adopted, let it be, like your work, indulged in with some sort of method, so that the one may not suffer but benefit as a result of the other. One is but too familiar with the opposite extremes between which, of course, lies the happy mean. One student thinks of absolutely nothing but his work; from morning until night, week in, week out, Saturday afternoon and Sunday included, no relaxation is taken. A student of this class was positively met on his way to the College, with a femur under his arm deep in the contemplation of its inferior extremity. On the other hand, who has not come across the student who, from all appearances is endeavouring to qualify rather as a professional cricketer than as a practitioner of medicine. In this matter I cannot do better than recommend to your consideration the advice lately given by the Master of Trinity, which you will not appreciate the less because it was addressed to a gathering of school boys: "Strive to preserve a right balance between your different enthusiasms." Cultivate the habit of throwing off all thoughts of work at the proper time for recreation, but do not let the latter so occupy you that the more serious matters which should be your first concern are relegated to spare moments when there seems to be nothing else to do. Football and cricket will, of course, take precedence of all other games, and of these the former certainly has the advantage that it can more easily be indulged in without interference with the work of the school. Moreover, football offers the additional advantage that it often combines pleasure with business and affords no small experience in the rendering of first aid to the wounded and a valuable personal acquaintance with the more ordinary fractures and dislocations.

In such an institution as this we necessarily miss much of the social life of a university. A man may, if he be so disposed, pass through the whole of his career here and never know in any real sense a single one of the men with whom he is daily brought into contact. But although such a state of things is possible it is none the less undesirable and by no means necessary. The man who locks himself up within the narrow limits of his own self is denying himself one of the most valuable means of preparation for his part in life. We are all more or less roughly-cut stones—though some perchance be diamonds—and are much improved by gentle friction with others of a like kind. In his work the student will necessarily find himself in constant association and competition with his fellows, and the wise man will not allow any feeling of jealousy to lessen the valuable assistance which he can gain from intercourse with those who are stronger than himself. How exactly does R. W. Emerson hit off what all of us must feel in this matter of friendship. "Our chief want in life is somebody who shall make us do what we can. This is the service of a friend. With him we are easily great. There is a sublime attraction in him to whatever virtue is in us. How he flings wide the doors of existence! What questions we ask of him! What an understanding we have! How few words are needed! It is the only real society."

> "He who has a thousand friends
> Has not a friend to spare,
> And he who has one enemy
> Shall find him everywhere."

Let us then, for our general and individual advantage, do what we can to promote real friendship amongst us. There can be no doubt that many a man has been driven to something approaching despair and has sadly failed in his work for want of nothing more than a real friend to whom he could have gone with his troubles and anxieties and by whose help his way might soon have become smooth again.

Let me here recommend to you the many societies which we have in this college, and of these more particularly the Medical Society. Since its formation in 1828 this has done excellent work. By all means join it, attend its meetings, and do not be a silent member. It affords excellent schooling in the art of speaking—a gift which, unfortunately, so few of us possess. We know exactly what we want to say, but once on our feet we do little more than perspire and splutter and lose our heads; the carefully thought-out sentences rapidly vanish; forty are begun but none ended; until, finally, we sit down, flurried and trembling, leaving our audience in the most blissful ignorance of what we hoped to convey to them. It is a gift worth much pains to acquire to be able in a few clear words to express our meaning, and the medical man will find it particularly useful if he can do this without the use of phrases which to the lay mind may be perfectly unintelligible.

To those who to-day are about to begin their practical work in the hospital how much might be said. Let us ever bear in mind that a hospital such as ours fulfils two great functions. In the first place it is a charity, and in the second place it is a training-ground for students of medicine and a centre for the advancement of medical knowledge—two functions of the greatest importance to the community at large. Now, contrary to what many persons seem to imagine, there can be no doubt that the work of the charity is all the better performed by reason of its connexion with a medical school—I mean that the presence of students in a hospital is certainly an advantage, and not a disadvantage, to the patients. I do not speak only of the many duties which the students in a hospital perform under the direction of the medical officers—duties which are all the better done by reason of that feeling of responsibility which, especially when first appreciated, is such a strong incentive to good work. I refer to the healthy criticism which stimulates into action the best efforts of those upon whom it is brought to bear. Who will venture to deny that a physician or surgeon sitting in the out-patients' room, and for several hours attending to the various complaints of the patients who come before him, will not do his work better and with less risk of some serious oversight when he is surrounded by a group of earnest students than when he works uncriticised and unobserved?

In his clinical work in the hospital the student will find that those habits of method and thoroughness which he has contracted in his earliest studies will prove of the greatest value to him. The two great faculties which the student of medicine should strive to cultivate are, first, the power of accurate observation, and, secondly, the power of drawing accurate conclusions from the facts observed—faculties not different from those aimed at in any form of education, general or special. In speaking of the education of the young it has been observed that "scientific training is not the imparting to others the results of someone else's observations, but the developing in every individual child a mind capable of making its own observations and of drawing its own accurate conclusions. It is not how much a child knows that matters, but how much a child is able to find out and learn for himself." It is better to have a store, scanty though it may be, of carefully made personal observations than a brain loaded to the full with facts said to have been observed by other people. From the very vastness of the subject it goes without saying that the student of medicine will find himself compelled to accept as true many facts which he has not the opportunity of verifying for himself, but these should not be one more than necessary, for they lack that reality which serves to impress facts personally observed. Gentlemen, no period of your career can compare as a training in the art of observation with that which is spent as clerks and dressers in the wards of the hospital. The cases with which you will then be individually concerned will, if rightly observed and investigated, serve as a very sure foundation of your experience of disease. Each case should be followed through with the utmost care, and no detail, however insignificant it may appear, passed by unnoticed. In many instances it may appear to you as though the elaborate details of the written records of the cases, for which you will be in part responsible, are superfluous, and the preparation of them a waste of time. There can be no greater mistake. The training thus obtained in the observation of the symptoms and physical signs of disease is invaluable, and even should the result of your labours be to show that the supposed patient is in reality sound, the time you have spent in coming to this conclusion will not have been wasted. You will often be called upon to decide whether an individual is in a state of health or disease, and before you are justified in stating that to the best of your belief no evidence of disease is present you must have left no stone unturned in your examination. There can be no doubt that many more mistakes in diagnosis result from incomplete examination than from faulty deduction. The latter is excusable, although serious; the former is less serious, but quite inexcusable. Each case thus thoroughly investigated and recorded will become fixed indelibly in the memory and will serve as a standard with which similar cases afterwards met with can be compared.

Digitized by Google

In this way alone can a living picture of a disease be obtained which will subsequently be of practical value. The knowledge thus gradually accumulated must of course be supplemented by systematic reading, but this must be kept in its right place and not allowed to take precedence of clinical work. The man whose only acquaintance with disease is that which he has obtained from the pages of a text-book is trusting to a broken reed, and it is proverbial that those who have the greatest store of book-learning are by no means always those who are best able to apply it practically, so that their opinion as to the nature and treatment of a case may be vastly inferior to that of a man whose knowledge, though much less than their own from the point of view of quantity, has been derived from practical experience. Therefore, above all things let your resolve be to see things for yourselves and not to take other persons' words for them. One case thoroughly investigated is worth more than a hundred merely seen.

From the day of its foundation thoroughness in clinical work has ever been the pride of University College Hospital. The hospital is not a large one and, comparatively speaking, is never likely to be, and yet some of the first clinicians of the last half century have received their training within its walls. But whilst urging the paramount importance of a few cases thoroughly observed I would not for a moment under-estimate the value of an abundance of clinical material. No two individuals even in a state of health are exactly alike, and still less are two examples of the same disease ever precisely similar. Every case will exhibit something new and will differ more or less widely from the standard or type with which we compare it, and thus we see the need for the cultivation and exercise of a wise judgment. This alone will serve to distinguish between the fundamental and the superficial. It often happens that the most obtrusive symptom which a patient presents, and of which he himself may chiefly complain, is of small importance as a guide in diagnosis compared with some less obvious sign apparent only to the trained observer. We very rightly entertain the greatest admiration for the man who possesses in a high state of development the gift which we call "clinical instinct." By this he is enabled often with astonishing rapidity to form a correct opinion of a difficult case by a process of the steps of which he is himself scarcely conscious. The ideal clinical teacher is he who not only possesses in a high degree of perfection this clinical instinct, but is also able to analyse for those who are less gifted than himself the train of argument by which he arrives at his conclusions. It is useless for the student to attempt to imitate such brilliancy, much as he may admire it; it is enough for him to keep a strict watch over his power of reasoning and satisfy himself that he has a good sound basis for any conclusion at which he arrives. By such means alone can he hope to gain any firm belief in his own opinion, and, having formed it, to stand by it resolutely, but not pigheadedly. Carlyle tells us that the gift which we call *genius* enables a man to express "what all men were not far from saying, were longing to say." Therefore, I take it, we should all be something more nearly approaching geniuses than we are if only we had the courage to say what we think or are longing to say. Let us learn, then, as Emerson bids us, "to abide by our own spontaneous impression with good-humoured inflexibility then most when the whole cry of voices is on the other side; else to-morrow a stranger will say with masterly good sense precisely what we have thought and felt all the time, and we shall be forced to take with shame our own opinion from another."

It may not be out of place for me to remind you of the necessity of being very broad-minded in your medical studies and of not allowing any special liking or aptitude for some particular branch to cramp your efforts in other directions. It is sufficient for the present that your aim should be to obtain such a sound general knowledge of the principles and practice of medicine and surgery as the few short years at your disposal will allow. This is an age of specialism, and before you know the names of the bones your relations and friends will be asking you what particular branch of practice you intend to adopt. Tell them "general practice" and let this be your aim. Specialism is absolutely necessary on account of the enormous scope of the science of medicine, and men must be found who will limit their efforts mainly to special branches, and by so doing attain to a degree of special skill and knowledge which is impossible to the general practitioner whose sphere of work knows no such narrow limits. The point, however, which at the present day seems to require more full appreciation is that no man has a right to style himself a specialist until he has already shown himself possessed of the knowledge required to equip him for general practice. In fact, some of the most celebrated specialists who could be named spent their earliest years in general practice until a special taste or success in some particular department led them to devote their attention exclusively to it. A specialist should know everything that is known about something, and something about everything else, whereas too often he knows something about something and nothing about anything else. Cavities have a natural charm for him, and gradually his view of life is apt to narrow itself to that which can be obtained through the particular speculum suited to the particular orifice which he has appropriated to himself. He becomes in course of time like the blind crabs in the caves of Kentucky whose eye-stalks still remain, but whose eyes have long since disappeared for want of use. A story is told, for the truth of which I would not vouch were it not transatlantic in origin, of an urinary specialist of this type who explained the presence of an ingrowing toe-nail as the result of the impaction upon the digit of an urinary calculus which he felt sure the patient unconsciously had passed per urethram. Every medical man who is not in general practice is a specialist, although the limits of his special branch may vary much in different instances. His proper function is to serve as a referee for the general practitioner in special cases, and it is certain that the public will live to regret it if they go too far in deserting the good old custom of entrusting themselves to the care of the well-tried family medical man and instead allot their various members and organs to the charge of special custodians. Turn to Oliver Wendell Holmes's "Over the Teacups" and hear what conclusion the Counsellor's friend came to: "Following my wife's urgent counsel I kept on for a whole year with my specialists, going from head to foot, and tapering off with a chiropodist. I got a deal of amusement out of their contrivances and experiments. Some of them lighted up my internal surfaces with electrical or other illuminating apparatus. Thermometers, dynamometers, exploring tubes, little mirrors that went half way down to my stomach, tuning forks, ophthalmoscopes, percussion hammers, single and double stethoscopes, speculums, sphygmometers,—such a battery of detective instruments I had never imagined. All useful I don't doubt, but at the end of the year I began to question whether I shouldn't have done as well to stick to my well-tried practitioner. When the bills for 'professional attendance' came in, and the new carpet had to be given up, and the old bonnet trimmed over again, and the seal-skin sack remained a vision, we both agreed, my wife and I, that we would try to get along without consulting specialists except in such cases as our family physician considered to be beyond his skill."

We are indeed at the present day possessed of a wondrous "battery" of means for the investigation of disease, many of the greatest value, some requiring much skill for their right application, but all worthy of our most careful study. The physician who suspects tuberculosis proceeds to search for the bacillus tuberculosis in the secretions and discharges and may even resort to experimental inoculations; he confirms his diagnosis of typhoid fever by observing Widal's remarkable reaction, and in a doubtful case of diphtheria forms his decision by noting the character of the growth of micro-organisms obtained from it. The surgeon calls in the aid of the microscope to clear up his doubt as to the nature of a tumour; he trusts to the Roentgen rays to tell him whether he is correct in his diagnosis of fracture; and frequently has resource to that valuable, but sometimes abused, investigation—an exploratory operation. All these and many other such methods are of the greatest value if rightly used, but there is just this fear that in our eagerness to resort to them we may at times be inclined to neglect those more ordinary methods of examination which can be conducted by the skilled eye, the educated touch, and the trained ear. Let us not use our naked eyes the less carefully because we are enabled when necessary to supplement them by oil-immersion lenses, not pay less regard to all the clinical features of some obscure abdominal tumour because in the end we intend to expose it by operation and see what it really is.

Gentlemen, I must soon close or you will be inquiring whether my vocation in life is to preach or to practise, but before doing so I would ask you to bear in mind that you will lose much of the value of your hospital work unless while you are learning how to deal with disease you learn

Digitized by Google

also how to treat the patients. Be kind and courteous to them, for an ailment which to us may be trivial and possessed of but little interest is to them a very real and serious affair, and they will naturally be disappointed and distrustful if they notice that we regard it as a matter of little concern. Much patience and tact are often required to extract the information we require, whilst considerable skill is often called for rightly to interpret the answers to our questions. It is needless to say that no gentleman will adopt one plan of treatment for the poor in the hospital and another for the well-to-do outside it. Further, the student, whilst performing the duties of even the most humble appointment, should appreciate the fact that the work he does will reflect either to the credit or discredit of his hospital, according as it is carried out thoroughly or carelessly, and that a very little pains more or less on his part may make just the difference to the comfort and welfare of the patients with whom he deals. Those who after receiving their qualifications are fortunate enough to obtain resident appointments in the hospital cannot too fully appreciate the responsibility of the position they occupy. In duty to themselves they should endeavour not to miss a single one of the many advantages for practical study which hospital life affords them. In duty to the institution they must recognise the dignity and grave responsibility of the work which they have voluntarily undertaken. In duty to the more junior men, who will take their standard from them, they must be punctual, thorough, and painstaking; for of this I am sure, unless a remarkable change has occurred in the few years since I was a student in the hospital, that the clerks and dressers look more to their house physician or house surgeon than to the members of the staff for their first lessons in the practical aspect of their work, and the resident officer who neglects this part of his duty is missing a splendid opportunity, for there is no better way of teaching oneself than by endeavouring to teach others.

We are rejoicing to-day in the magnificent service which Sir Blundell Maple has done to University College, and many of you will have the privilege of enjoying at least some of the advantages of the new hospital. Since the day of its foundation as a humble dispensary on Sept. 28th, 1828, University College Hospital can show a record of work of which we may well be proud, and it is not without a passing pang that we realise that the old building will soon be numbered among the things of the past. May a double portion of the spirit of energy and enthusiasm which has stimulated our workers in the past fall upon those who shall be privileged to carry on their labours among the far more favourable surroundings of the future. May we never merit the reproach that we have missed the splendid opportunities which lay before us. Gentlemen, we pride ourselves on our past achievements, but we must not live upon them alone. The future is ours, and we have the making or the marring of it. It is to you, gentlemen, who year by year come forward with fresh instalments of enthusiasm that the College looks to make her reputation in the past an earnest of great deeds in the future. Were I possessed of the highest eloquence and powers of oratory they should all be employed in my endeavour to fire you with enthusiasm. Successes and failures must come to each one of us. Let success be an encouragement to further efforts and not an inducement to rest upon the laurels gained. Let failure not dishearten us, but rather stimulate our energies to follow it with success. And if at times you feel despondent do not give way to despair—"Look not to the mournful past—that comes not back; wisely improve the present—it is yours; go forth into the future without fear and with manly heart."

HOME FOR CRIPPLED CHILDREN AT GOSFORTH.—A new Home for Destitute Crippled Children was opened at Gosforth, Northumberland, on Sept. 30th, by Mrs. Hilton Philipson, who unlocked the principal door with an ornamental golden key in presence of a large and influential gathering. The institution provides accommodation for 110 boys and girls; it has cost about £10,000, and continues the work of the former home at Wallsend. The annual report was read, in which it was stated that the building fund had reached a total of £8500, leaving about £1500 still to be raised. Mr. Hilton Philipson had contributed £2000 to endow five cots, in addition to a sum of £1100 which was given by him at the commencement of the home's career in Wallsend, and which formed the nucleus of the building fund.

Remarks
UPON
CANADA: ITS CLIMATE AS A HEALTH RESORT AND ITS POSITION TOWARDS MEDICAL SCIENCE.

Being the Introductory Address delivered at the Middlesex Hospital Medical School on Oct. 4th,

BY LORD STRATHCONA AND MOUNT ROYAL, G.C.M.G., &c.,
HIGH COMMISSIONER FOR CANADA, AND CHANCELLOR OF MC GILL UNIVERSITY, MONTREAL.

GENTLEMEN,—While appreciating most fully the honour of being asked to address the students, past and present, of the Middlesex Hospital School and to distribute the prizes I must confess that my idea of what the duty of doing so involved fell far short of the reality. It occurred to me that at the most a few words of a more or less formal character would be all that was needed, and only quite recently did I begin to realise what is expected on such an occasion. A little more consideration, instead of consenting rather hurriedly to comply with the request, might have led me to hesitate to accept the very kind and flattering invitation of the Council conveyed to me through Dr. Pasteur, the Dean, especially now that I call to mind the eminent men who have preceded me in the position. Yet I am glad to be here, since I regard the medical profession as one of the noblest of all the professions in view of the great service it has rendered, still renders, and unquestionably will continue to render, more and more to mankind. And, again, no one more thoroughly recognises than I do the immense utility — indeed, the absolute indispensability of the great hospitals — among which the Middlesex Hospital has played so important a part for over a century and a half. They supply the best medical advice and assistance to those among our suffering humanity who are not able to pay for the attention they are thus enabled to receive gratuitously; and the opportunities they afford of raising to a still higher standard education both medical and surgical, and in connexion with the training of skilled nurses—now so essential an adjunct to the medical profession—cannot be over-estimated.

It has been my privilege within the last few weeks to be in Canada during the meeting of the British Medical Association in Montreal, and I am glad to be able to refer to its success from every point of view. It was a happy idea that such a *réunion* should take place in one of the outlying portions of the empire, especially in the present year, when Imperial sentiment seems to have shown a vigour not previously witnessed, and when the Dominion of Canada and the colonies of the empire have been brought much more closely towards the mother country than they have ever been before. The fact that two great associations like the British Association for the Advancement of Science and the British Medical Association should both in one year hold their annual meetings in Canada is proof in itself of the improvement that has taken place in the means of communication between the different parts of the world. It tends further to show the colonies that the term "British" includes them, and that they are as much a part of the empire as any of the counties or divisions of the United Kingdom. Nothing but good can result from the opportunity of the interchange of thought between the medical men of the United Kingdom, Canada, and the United States, and I venture to think that the greatest possible benefit will follow the recent successful meetings of these important bodies. We were delighted to welcome the British Medical Association in Canada for many reasons. It was doing the country an honour that they should visit us, and it was felt also that the occasion would afford the opportunity to a large number of men of light and leading in the medical profession to form an idea of its climatic advantages, of its position as a health resort, and as a new field for travel in the case of those requiring both rest and change—without the necessity of giving the change to the waiters and the rest to the keepers of the hotels, which has

Digitized by Google

humorously been said to be the net result of a good deal of the foreign travel which takes place. In the western districts of Canada—that is, on the prairies—the air, from the altitude of the plains, is very dry and bracing, and a stay there has been found to be very beneficial in cases of lung and chest troubles. This is becoming recognised in the United Kingdom, and many persons who have suffered from pulmonary complaints and affections of the kind have been practically free from them while staying in the Dominion. This is also the case in the Rocky Mountains, among the pine forests, and the Kamloops district; and the establishment in that district of a large institution in the nature of a sanatorium is seriously contemplated. There are likewise medicinal springs to be found in places, not the least known among them being the sulphur springs of Banff, where water of a temperature of 100° and upwards flows from the sides of the mountains. They are now visited by invalids from Canada and the United States, and no doubt their fame may some day extend to England. Canadians are proud of their country. They are anxious that it should be better known among their fellow subjects in the mother land than it is to-day, and we are quite certain that those ladies and gentlemen who visited the Dominion this year as members of the two associations already referred to will return with feelings as warm as our own for what we regard as not the least important part of the British Empire.

The practical annihilation of space resulting from improved means of communication was strikingly illustrated to me a few years ago during the lifetime of my late dear friend, Sir Andrew Clark. A young man of good family was taken seriously ill in British Columbia. He was in a critical condition, and his friends were naturally most anxious about him, especially in view of the 6000 miles that separated them. It was arranged by the courtesy of the Cable Company to have a conversation between London and Victoria during the night—Sunday night it was—when the cables and telegraphs were not much engaged. Sir Andrew Clark kindly framed some questions to be put to the medical adviser of the distant patient. From the office in London messages were interchanged as rapidly as they could be transmitted, the symptoms were explained, and the treatment discussed, and I am happy to say that the young man recovered. Of course, I do not mean to imply that this was the direct result of the telegraphic communication, but it enabled the friends of the young man to be assured that everything possible was being done for him, and the practitioner in Victoria had the benefit of the opinion and advice of the eminent and good man with whom it was my privilege to be on terms of friendship for many years.

You will, I think, be interested to learn that the training of the medical profession in Canada has made much progress in the last few years. Year by year large numbers of young men are trained and qualified in practice, and many of them visit England and the Continent after obtaining their degrees in order better to prepare themselves for the important work to which they propose to devote their lives. The excellence of the instruction given in Canada and of the clinical advantages that are available are demonstated by the fact that it is the exception for any of the Canadian graduates to fail in the examinations for degrees on this side. There are eleven medical schools in Canada. The oldest as well as the largest is that of McGill University, Montreal, which is now entering upon its sixty-seventh session. Many of the requirements and advances in medical education on the American continent were first instituted there. It is the only Canadian medical school that has an endowment (derived from benefactions from the citizens of Montreal), the others being dependent on the students for carrying on their work. All the Canadian medical schools require a four years' course, with sessions of from eight to nine months, and the methods of teaching follow closely those of the English and Scotch schools. The Faculty of Medicine at McGill is always kept up to date. The latest improvement is the equipment of the Museum of Public Health, and considerable additions have also been made to the Laboratory of Experimental Pharmacology. It is now four years since the department of hygiene was established, and part of the interest of the endowment was set aside to provide a Museum of Public Hygiene and Preventive Medicine. This has been allowed to accumulate for the last few years in order that a sufficient sum might be available to make a good start. The museum occupies three rooms in the medical building, and at present is chiefly of interest on account of the number and excellence of the working models illustrating the best modern methods of sterilisation, disinfection, filtration, and ventilation, together with a very useful collection of modern sanitary apparatus. It is expected that the museum will be found of great advantage in connexion with the lectures on public health, which for the future are to be regularly given. The students have also the advantage of the pathological laboratory at the Royal Victoria Hospital, which is admitted to be one of the most complete and instructive of any to be found either in America or in this country. While touching upon the question of education it is right to mention that medical students in most parts of Canada have the advantage of attending many excellent hospitals in the different centres of population. This is especially the case in Montreal, and members of the British Medical Association are said to fully appreciate the work that is being done by hospitals in that city and the manner in which the institutions are equipped. Some of the Canadian hospitals will compare more than favourably with institutions of the kind in the provincial towns of the United Kingdom, and even with many of those to be found in the great metropolis. Within the last few years, also, the training of nurses has attracted much attention, and numbers of these devoted women are to be found pursuing their noble work in every part of the country.

I regret I am not able to say that the position of the medical profession in the different provinces of Canada is as satisfactory as it might be in some respects. Licences to practise are issued by the medical boards in the different provinces, but they are only tenable in the provinces in which they are granted. A graduate in one province could practise in another on carrying out the local conditions, but in my judgment a licence issued in one part of Canada should entitle the holder to carry on work anywhere within the limits of the Dominion, and, indeed, in any part of the empire. The granting of authority to practise medicine should be under the control of a Dominion medical board as a matter affecting the community in general, and there should be uniformity in regard to the standard of study and the qualification to practice. The absence of facilities of this nature in Canada also operates to prevent Canadian medical men practising in the United Kingdom. They cannot be placed upon the registry for that purpose at the present time on the strength of their local qualifications until the Act of 1886 is extended by Order of Council to the provinces of the Dominion. This has not yet been done, as none of the provinces have passed the legislation necessary to enable reciprocal treatment to be extended to graduates from the United Kingdom. The matter is, however, receiving attention in the medical profession, and we trust it will not be long before the difficulties to which attention has been called are removed. No inconsiderable part of my life has been passed in some of the less populated districts of Canada where members of the medical profession were conspicuous by their absence. In fact, I hardly think I saw a medical man for a period of fifteen or sixteen years. Perhaps with some the introduction of the profession was not altogether popular, and there may have been an idea that when medical men were about complaints and sickness were rife and that little or no trouble of the kind existed and no malingering among the work-people when the medical man was absent. This no doubt resulted from the good health they experienced themselves in the salubrious surroundings of the northern climate in which they passed so many years of their lives.

You may be interested, perhaps, to learn something of the condition of things in the part of the Dominion to which I refer—the coast and inland district of Labrador—from the medical point of view, at any rate so far as they can be told by a layman. There is always a large mortality among the native children, resulting largely from lung diseases, and adults suffer a good deal from similar complaints. Rheumatism and affections of that kind are little known. Fevers are more or less common, but few of the organic diseases of civilisation are prevalent, and insanity and nervous diseases are more or less unknown. The people cannot be said to be long-lived, although exceptions occasionally occur, and from fifty to sixty years is regarded as a good age. It is very rare that one sees a bald head among the natives, and the hair does not change much in colour with age. So long as the natives keep to their own food and habits—they live largely on meat and fish, always cooked, and upon wild berries and fruits—they

Digitized by Google

generally retain their teeth. In fact, I have seen teeth worn almost to the gums without showing signs of decay. But in the case of the natives from the interior who adopted the food of the white men they soon lost their teeth; and from indigestion, and it may be from other causes incident to the change of living, their lives were often shortened. Although the climate is severe and the summers are short the country is healthy, and no doubt the open-air life conduces to freedom from disease. With regard to the treatment of disease they have their own remedies. A form of Turkish, or rather vapour, bath has been in vogue among the natives as far back as we have any records. They rig up a small tent, put stones that have been intensely heated inside and pour water upon them, and then take the bath. This is regarded by them as the most beneficial treatment in many complaints. They have also their decoction of herbs and they understand the preparation of nourishing foods, which are given in cases where there is a failing of strength and vitality. In the case of lung diseases they have much faith in the virtues of a decoction made from boiling crushed bones and marrow, and it is largely used. Small-pox is, of course, known, although fortunately it is not common, and vaccination has been accepted by the Indians cheerfully as a preventive measure. Amputations are occasionally performed by the natives themselves, or by the European and Canadian residents, in a primitive way. This is inevitable in that part of the country where medical men are often hundreds of miles away, but in this connexion I must refer to the improved state of things which has resulted in the last few years from the organisation of the Medical Mission to Labrador under the auspices of the Deep-sea Mission, whose hospital steamer patrols the coast during certain seasons. The mission extends medical relief to the inhabitants requiring it, and provides limited hospital accommodation throughout the year at one or two places.

It may interest you to know that what may be termed a primitive and somewhat rude form of antiseptic treatment was practised in the district many years before Lord Lister introduced his great discovery. For the treatment of wounds, ulcerated sores, &c., a pulp was made by boiling the inner bark of the juniper tree. The liquor which resulted was used for washing and treating the wounds, and the bark, beaten into a plastic, pliable mass, was applied after the thorough cleansing of the wound, forming a soft cushion lending itself to every inequality of the sore. Scrupulous cleanliness was observed and fresh material used for every application. It will, I think, be admitted that this is essentially the basis of the antiseptic treatment which is now so important, and with which the name of Lord Lister will ever be honourably associated. It shows that while discoveries and inventions are being made in centres of the highest civilisation they may yet be practised in a primitive way in distant and more or less inaccessible localities of which scientists may at the time be unaware. Perhaps I may be permitted to relate to you another little interesting experience which came to my notice. On the Labrador coast thirty or forty years ago there was a serious outbreak of scarlet fever accompanied with diphtheria. Many of the people died, both children and adults, and the survivors were so alarmed by the spread of the disease and its fatal results, and were in such an abject state of fear, that they kept away from the houses in which people were known to be suffering. There is little doubt in my mind that many of the persons died from simple dread of the disease and the fright occasioned by the mortality. An officer of the Hudson Bay Company visiting the settlement found this state of things existing. It was reported to him also that the family of a former employé of the company, a Scotsman, had taken the disease at a place some twelve miles distant. The official mentioned went there and found the whole family confined in a small hut, the different members being scattered over the floor, and, in fact, in any place where room could be found. The door was shut and so were the windows, and the odour that came when the door was opened can best be left to the imagination. One of the family, a boy, had died, and was lying in an outhouse. The first thing to do was to break open the window and let in air, and then to administer some remedies. All the other members of the family recovered, and the utter helplessness and abject terror which had previously prevailed among the inhabitants were at once changed into a feeling of hope. They saw that death was not inevitable, and, happily, although the disease still lingered on for some time, not a single fatal case was subsequently recorded. I merely mention this to show the moral effect of the return of confidence, which resulted from the death record having been temporarily stopped by the exercise of a little common sense. Another curious incident comes to my recollection. A resident in the country returned to England in consequence of a severe illness. He consulted the best medical men, and his case was diagnosed as one of Bright's disease. He was told that he could not last more than a few months, and made up his mind to return to Labrador to end his days; but the unexpected happened, and he lived for many years afterwards. Some of the natives knowing of his complaint, or, at any rate, of the symptoms, advised him to prepare a decoction from the juniper shrub and to drink nothing else for several months. In despair he did what was suggested, and after some time appeared to be perfectly cured. It is not claimed, of course, that the recovery was due alone to the efficacy of the remedy; it may have been that the case was imperfectly diagnosed or that a mistake had been made, but the circumstance shows the local belief in native remedies, and that not a little attention is paid to natural medicine and to the properties of the trees and shrubs which are found in the country even in the absence of any skilled knowledge of botany or experience of medical science.

A point suggests itself to me which may not be without interest to some of you. It is in connexion with the relative value of a meat and fish diet in respect to health and sustaining powers. A very general belief prevails, I think, that meat is the more nutritious and strengthening of the two, but this is not borne out in the experience of the Hudson Bay Company. In former years in certain districts the food of the employés was almost solely the flesh of the buffalo, deer, &c. In others it consisted mainly of fish. Opportunity was offered for testing the merits of the different foods each spring when the brigades of boats were on the way out with their furs. In these circumstances there were naturally trials of strength in rowing, and in the result the fish-eating crews invariably had the advantage, especially in long-sustained efforts. This proves, it appears to me, that theory and practice in these matters do not always coincide.

I hope I am not wearying you with these little incidents which I have come across during my life in Canada, but it has been suggested to me that I might relate to you an experience that came under my observation as showing the tenacity of infection, although it relates to animals and not to human beings. About forty years ago there was an epidemic among the dogs in the Arctic regions, and I need hardly impress upon you the consternation which it caused, seeing that in those parts of the world the dogs provide the only means of communication between the different districts during the long winter. The disease, which was not the ordinary distemper, came from the far north, indeed, as far north as the Esquimaux were to be found, and gradually spread itself south along the Labrador coast in the course of two years. The dogs which caught the infection were seized with vertigo and within a few hours death ensued. I knew of a dog that had not been within 100 miles at the time of any infection. An Esquimaux, however, arrived one day in the depth of winter, after a journey of more than 100 miles, which took him about eight or ten days, and in the intervening period he had not been in contact with any dogs. On his reaching the place the dog, knowing him, jumped upon him and gambolled about. The next day it was taken with the malady and in a few hours was dead. The assumption is that the man's wallet, in which he carried his letters and belongings, had been in contact with dogs at other places, and that the infection was conveyed in that manner, notwithstanding the intense cold which prevailed. It might be mentioned as a curious coincidence that only the native dogs suffered from the affection, whatever it was, and that dogs of the smaller types escaped either entirely or at any rate with slight attacks. As already suggested, the Hudson Bay posts became in a way medical centres in the districts in which they were established. The officers, for their own benefit and for the benefit of the natives, tried to acquire a certain amount of medical skill from text-books, and of course they were supplied with the simple remedies for certain diseases. They were also called upon to practise surgery, amputations having occasionally to be performed, especially as the consequence of the extremities being frozen in the severe climate of the far North. Many of them acquired more than a local reputation,

Digitized by Google

and there is reason to believe that bread pills and simple lotions, accompanied by faith, have effected marvellous cures.

But I am sure you have had enough of these personal experiences, and I should like to take the advantage of saying a few words on the subject of Canada. The proportion of medical men is fairly large in the Dominion, although not so large as in the United States. There are, however, large parts of Canada, particularly in the West, that are not yet occupied. That they will afford homes to millions of people in the more or less near future is as certain as that I am standing here, and there will thus be new fields continually being found for the activity of the students graduating every year, the numbers of which are ever on the increase. At the same time we do not encourage young medical men to go out from this country to Canada in search of employment for their skill unless they have friends in the country or are not dependent upon immediate work for their subsistence. The demand for medical men is amply met by the supply on the spot, although the old axiom that there is always room on the top of the ladder applies equally to Canada as elsewhere. You have no doubt seen recently that the few medical officers in the newly opened up goldfield of the North-West Territories in the Yukon district seem to be reaping a golden harvest, and £40 a visit has been mentioned as a common thing. I hope this will not encourage any of my audience to go out this year. The country is difficult of access, the mode of living is necessarily rough, and the expenses are great, so that notwithstanding the high fees that may rule for a time (and they can only be temporary) there are compensating disadvantages which have to be carefully considered.

In conclusion, will you allow me to say that in my opinion it cannot be too strongly impressed upon medical students that an important heritage descends to them, that they have to maintain the reputation of the school, built up by those distinguished men who have gone before them, and that great opportunities are open to them, as the result of their studies and investigations, of making life more pleasant and happier. It is only right, in my judgment, that the qualifications of graduates should be submitted to a severe test before they are allowed to practise; and, on the other hand, it seems to me to be a duty belonging to our legislators to see that persons without such qualifications are not let loose upon the community. Further, it is surely desirable that every proper means should be used to prevent quackery and to restrict the wide and unrestricted advertisement of nostrums. In fact, I should like to see a great deal more done to protect, promote, and encourage, in the interests of mankind, the beneficent work of the medical profession. Eminence in your profession, or, indeed, in any of the higher walks of life, cannot be attained without much labour and application. Indeed, it has been said that medical men must always remain students, and no one who has thought of the subject at all will dispute the statement. May I therefore venture to earnestly impress upon my audience the necessity of steady work and perseverance? It may appear at times tedious and tiresome, although such feelings are almost impossible when one's heart is in one's work. But success cannot be attained without effort, and for the ambitious man, the man who wishes to build up a reputation and to improve the condition of his fellow men, I know of no more attractive and inviting field than that offered by the medical profession. Besides, there is the competition which has to be faced in modern times. This may be good for the community, but it is also good for the profession, for the man of ability, the man of method, the man of investigation, must always come to the front. We often hear of certain persons of transcendent ability. In almost every case it is known that such a reputation has been made by indomitable perseverance and by abiding application, and does not so much depend upon any inherent pre-eminence in the individual. I trust you may agree with me in thinking that the attainment of the highest standard is open to the majority of our fellow men—that, given a sound body, ordinary intelligence, and a fair education to start with, any man who applies himself with all his might, and who will allow nothing to draw him aside from his purpose, may, apart from that ethereal, and might I dare say mythical, thing called genius, succeed in doing whatever others have been able to accomplish. At any rate, it is always safe for a young man to keep such an ideal before him. It is far from my desire to preach, but I have lived a good many years, and I am sure that what is true in other professions applies with much greater emphasis to the medical profession. I have only now to thank you very much for the patient hearing you have given to the disconnected remarks I have ventured to make, and to assure you that I shall always take great interest in the welfare and success of the Middlesex Hospital and of its medical school.

A THEORY OF ACTIVE AND PASSIVE IMMUNITY FROM THE BACTERIA OF CHOLERA, TYPHOID FEVER, AND THE LIKE.

BY PROFESSOR MAX GRUBER,
OF VIENNA.

Communicated by HERBERT E. DURHAM, M.B., B.S. CAMB., F.R.C.S. ENG.

THE experimental observations which have been made by myself, conjointly with Mr. Herbert E. Durham, during the last eighteen months upon the microbes of cholera, typhus abdominalis, &c., lead to the following conclusions in regard to the origin and nature of the immunity produced by means of these microbes:—

1. A high degree of long persisting immunity can be obtained by means of intra-peritoneal injections (in guinea-pigs) of microbes killed either by chloroform or by exposure to a temperature of 60° C. Such killed cultures of cholera, and other vibrios, of typhoid, and coli bacilli, &c., have little or no poisonous properties; the guinea-pigs show trifling symptoms in the course of treatment; they recover rapidly, even when such large doses as 0·5 gramme per 1 kilogramme are eventually exhibited. The only constant symptoms arising from these injections are to be attributed to the peritonitis, which is caused by the proteins of the bacteria. It follows from these facts that the dead bodies of the bacteria are not poisonous in themselves; and, furthermore, that the immunising constituents of the bacteria are not identical with the bacterial toxins.

2. The animals, when immunised by this method against the above-named bacteria, are truly infection-proof, but they are by no means toxin-proof. At the present time we are not dealing with toxin-proof immunity; and we are far from saying that animals cannot be rendered proof against the toxins of the above-named bacteria by the use of suitable methods.

3. The destruction of the bacteria takes place through the medium of the juices in actively immunised animals as well as in animals which are protected passively by means of the serums of immunised animals. This fact has been correctly observed and emphasised by Pfeiffer. The (polynuclear) phagocytes only play a secondary and comparatively unimportant part in the process.

4. Protective or antagonistic substances (antikörper) are always present in the blood and juices of the immunised animals. They are already formed and are not suddenly produced at the moment that a further inoculation is given, as has been asserted.

5. Both in actively and in passively immunised animals these substances (antikörper) react directly upon the bacteria, whether the contact occurs within the body or *in vitro*. There is no evidence that they undergo any changes or transformations in conjunction with the normal juices when animals are protected passively by their aid.

6. These protective substances are the characteristic constituent of the blood and juices of immunised animals. They are not capable of actually killing the bacteria by themselves.

7. The actual destruction of the bacteria is effected in all animals, whether actively or passively immunised, by means of the alexins of Buchner. These alexins are general protective substances entirely without specific action; they are universally present in all animals. Phagocytosis only takes a secondary share in the destruction.

8. The essential action of the protective substances of the blood and juices of immunised animals consists in making the bacterial cell walls adhesive. This is shown by the fact that

Digitized by Google

the bacteria become sticky when treated by these juices; in consequence, they adhere together in clumps and lose their motility. This fundamental phenomenon in the action of protective sera has been entirely overlooked by Pfeiffer and his pupils (see note appended); it has been seen by Metchnikoff and Bordet, but they have neither recognised its importance nor its true meaning. On account of this fundamental action we propose to call the specific antagonistic substances of immunised animals "agglutinins."

9. The agglutinins act upon the sheaths of the bacteria and make them more penetrable. The alexins are enabled thereby to reach the bacterial protoplasm and to destroy it—in other words, to kill the bacteria. This process takes place quite indifferently inside the living animal or *in vitro*, the only condition necessary being that both agglutinins and alexins are present.

10. The agglutinins are used up during the process, perhaps by chemical combination or perhaps by actual destruction. It therefore follows that the extent of action of the juices of an immunised animal is directly proportional to the amount used.

11. Active immunity never occurs without evidence of the presence of agglutinins.

12. Active and passive immunity are identical in nature. Both forms of immunity depend upon the presence of agglutinins.

13. It has been asserted that active immunity persists even after complete disappearance of the protective substances—that is to say, after the tissue juices have lost the power of conferring a specific passive immunity. This in reality is only the expression of the fact that the degree of concentration of the agglutinins gradually diminishes as time goes on; eventually the proportion of agglutinins present is insufficient to be effective in producing passive immunity.

14. I have been able to prove the presence of agglutinins thirteen months after the last immunising injection. How much longer they persist I am unable to say, as at present I have not any animals which have been kept a longer time since their last treatment.

15 Agglutinins are specifically different. Each kind of bacterium has its own kind of agglutinin.

16. The influence of these specific agglutinins is, however, not limited specifically; it shows gradations in intensity of reaction, the maximum intensity of action being manifest upon its own kind. On other species the action is the more intense the more closely allied the microbe is to that by means of which the agglutinin was prepared.

17. Pfeiffer's assertion that an absolute specificity exists in the action of protective sera is not in accordance with, or supported by, observed facts.

18. The agglutinins are without doubt derived from certain constituents of the bacteria themselves (specific proteins?). They are produced only in the bodies of actively immunised animals, probably by combination with some constituents of the animal body. The site of production is perhaps in the macrophages; these cells ingest and destroy the polynuclear leucocytes which are laden with bacterial products.

19. The above conclusions are drawn from experiments with the microbes of cholera and allied vibrios, of typhoid fever, and the like. In diphtheria and tetanus other factors are probably present.

Note by Mr. DURHAM.—Professor Gruber has kindly invited me to give some of my own views on the subject of the above remarks. In the first place it must not be thought (*vide* Conclusion 1) that agglutinins are present solely in animals treated according to the manner described. It appears to be quite indifferent whether the bacteria used in the immunisation are living or dead in so far as the production of agglutinins is concerned; moreover, lately I have proved that immunisations carried on with germ-free filtered products also give rise to the presence of agglutinins. It goes without saying that the avoidance of inoculating with living microbes has great advantages in the immunisation of animals. With regard to the toxicity of the bacterial bodies it is interesting to note that Pfeiffer himself admits that the killed bacteria are not less than twenty times less poisonous than the living bacteria,[1] 12 milligrammes of killed culture being equivalent to 0·6 milligramme of living cholera vibrios, although he has long been the champion of the pretended great toxicity of dead bacterial bodies.

It must not be understood that the substances which we have termed agglutinins are only able to cause susceptible microbes to gather together in clumps or flocculi; they also act as inhibitors to the growth of the organisms, as also to the formation of metabolic products. For instance, pyocyaneous serum inhibits the formation of pyocyanin, and the serum of a phosphorescent vibrio can annul the phosphorescent power of this vibrio, as I recently demonstrated to the Fellows of the Royal Society. These and many other facts point to a weakening of the microbe by the direct action of the agglutinins upon them, and I cannot but think that this influence is exerted upon the bacterial protoplasm rather than upon the dead sheaths of the bacteria. It is well known that in the face of highly virulent microbes both alexins and phagocytes are unavailing, whilst with the microbes of a low degree of virulence these means are ample for ensuring the destruction of the microbes. By the use of an appropriate kind of serum an extremely virulent microbe can be made non-virulent in a few seconds, or possibly in less time, so that it degenerates when brought into contact with alexins.

I have shown that the requisite degree of weakening can be obtained by heating an emulsion of bacteria to a sufficient extent; the bacteria are then unable to withstand the alexins and they degenerate rapidly. That the protoplasm of the bacteria is the most important part of the micro-organism there can be no doubt, and the above facts appear to me to point to the conclusion that the prime action of the agglutinins is upon the bacterial protoplasm. This is further shown by the influence these substances have upon the naked protoplasm flagella of the microbes; the agglutinins paralyse their movement. In extremely diluted sera some individuals can be seen to stick to one another without doubt by their flagella; they rotate madly about their fastened extremity. So that it is evident we are dealing with something more than a mere increase of adhesiveness of the surfaces (sheaths) of the bacteria, which stickiness may, after all, be due to some sort of secretion.

Although the amœbocytes, especially the polynuclear leucocytes (*vide* Conclusions 3 and 7), only play second string to the extra-cellular agents in the destruction of bacteria, yet it must be admitted that their action as scavengers is by no means unimportant in ridding the animal of its unwelcome parasites. Personally I am inclined to regard the polynuclear amœbocytes as very important agents in the broad field of bacterial destruction. In my paper before the Royal Society, and in a paper which will shortly be published in the *Journal of Pathology*, I have avoided the term "specific" as inappropriate (*vide* Conclusion 15); in its place I suggest that the words "special" and "specialise" should be used as they designate the reality more accurately. In conclusion, Pfeiffer has quite recently shown that even after his long years of study on the "specific" action of the sera in typhoid fever and cholera he has at last recognised the fundamental fact of the action of agglutinins.[2]

ON FOUR CASES OF GOITRE TREATED BY OPERATION, AND CERTAIN DANGEROUS SYMPTOMS WHICH MAY FOLLOW THE OPERATION.[1]

BY A. J. RODOCANACHI, M.D. LOND.,
LATE HOUSE SURGEON, UNIVERSITY COLLEGE HOSPITAL.

THESE four cases of tumour of the thyroid gland were operated upon during the time I was house surgeon at University College Hospital. Three of the cases were under the care of Mr. Horsley and one was under the care of Mr. Heath. My purpose is especially to investigate the meaning of certain symptoms which were present in two of the cases with a fatal result in one—symptoms well known to

[1] A paper read before the Medical Society of University College, London, Feb. 9th, 1897.

Digitized by Google

all who have had experience of thyroid disease, but about which not much has been written.

CASE 1.—A married woman, aged forty-nine years, was admitted to the hospital on Feb. 20th, 1896. She had a very large cystic thyroid gland involving both lobes and causing serious dyspnœa by pressure on the trachea. The dyspnœa was very marked and prevented her from lying down, so that she slept propped up in bed. In spite of this she had continued at her work until a few days before admission, and she insisted on walking upstairs to the ward, but arrived at the top of the stairs in a very alarming condition. When quiet her pulse was 116 and her respirations were 40 per minute. On the next day Mr. Horsley operated. The right lobe of the thyroid gland, which was the larger, was dissected out through a free incision, all the vessels being clamped before they were cut. A cyst on the left side was afterwards enucleated, but it was ruptured during removal and a good deal of the pale brown contents necessarily escaped into the wound. The trachea was found much compressed—reduced almost to a slit. No irrigation was employed, but the wound was closed, a small drainage-tube being inserted at the lower end. The patient bore the operation very well considering her previous weak condition; there was but little shock and the breathing was immediately relieved. The wound was dressed at 9 P.M. (six hours after the operation). There was, as usual in these extensive operations on the neck, very considerable oozing, which had soaked through the dressing. The patient felt very comfortable, the pulse was quiet, the respiration had been relieved, and she expressed herself very hopeful as to the result. She continued like this in a quiet, comfortable condition, taking occasional sips of milk, until 1.30 A.M. Then suddenly her symptoms changed completely. She became extremely restless, tossing herself about in bed. This was the most striking symptom, as previously she had been a very tractable patient. The pulse ran up to about 180; the respirations became very rapid (from 50 to 60) and shallow, but not embarrassed; there was no stridor. Whereas previously she had been hopeful, she now declared she knew she was about to die—a declaration one does not treat lightly when coming from a person not known to be hysterical. The temperature, taken in the axilla, was found to be 99·2° F. I gave her three minims of morphia hypodermically in order to quiet the restless condition, hoping she might sleep off these effects and wake up better. She remained quieter for a time, but the symptoms returned and she was about as before only weaker when I saw her again at 3 A.M. I abstained from giving more morphia as already a fairly large dose had been ineffectual, but in the light of subsequent events it might have been better to have given it. At 6 A.M., about fifteen hours after the operation, I was called to her again, but found that she had just died.

Necropsy.—A post-mortem examination was made by Mr. Drew. The part of the thyroid gland removed was completely riddled with cysts separated by fibrous strands. The cysts contained brown colloid in parts, while in others they contained intra-cystic growth. Examination of the dressings and of the neck and chest showed that there had been no bleeding to speak of since the dressings were changed at 9 P.M., therefore the symptoms can obviously not have been due to internal hæmorrhage. A careful dissection of the neck showed that there had been no damage to any of the main nerves. The remaining lobe of the thyroid gland was found to be extensively diseased—in fact, similar to the part removed. The trachea showed signs of compression, it contained no blood, secretions, or other obstruction internally. The other organs were normal.

CASE 2.—An adenoma of the thyroid gland was removed by Mr. Horsley from a young neurotic woman. There were no cysts present. The wound healed perfectly and the patient got well without a bad symptom. She was admitted to the hospital on April 18th, 1896, and left on May 12th.

CASE 3.—Mr. Horsley dissected a solitary cyst from the thyroid gland of a boy aged thirteen years. The cyst was removed unopened. The wound healed perfectly and the boy never had a bad symptom. He was admitted to the hospital on April 27th, 1896, and left on May 9th.

CASE 4.—A woman, aged thirty-five years, had a cyst of the right lobe of the thyroid gland. She was admitted on June 8th, 1896. Mr. Heath removed the cyst through a small incision, it being necessarily ruptured during removal and the contents extravasated. Bleeding was stopped by plugging the wound with iodoform gauze. There was considerable shock after the operation. On recovering from the shock the patient was very restless, though not to the intense degree that the first patient had been. She got very little sleep and complained a good deal of pain. Her pulse before the operation had been 132. On the evening of operation, June 17th, the temperature was 99·2° F., the pulse was 100, and the respirations were 40. On the evening of June 18th—i.e., some thirty hours after the operation—the symptoms began to be alarming, the temperature had risen steadily to 101·3°, the pulse to 136, and the respirations were 36. I gave her three minims of morphia hypodermically. After this she slept continuously for eight hours and woke up in a very different state. She was cheerful, contented, free from pain and no longer restless. After this she made an uninterrupted recovery and left the hospital on July 17th.

The symptoms to which I wish to draw attention are essentially restlessness, a rapid pulse, rapid respiration, accompanied by a considerable amount of mental anxiety, with in certain cases a fatal result. I need say nothing as to the necessity of studying these symptoms so far as we can. Anyone who has witnessed them will carry away a very vivid if painful impression, and those who in the future may have the after care of cases from which thyroid tumours have been removed by operation should know what little is to be known in order that they should be alive to the importance and dangerous significance of the symptoms. In published literature there is not much directly bearing upon the matter. In Erichsen's Surgery there is no mention of this group of symptoms among the dangers of operation, whether for ordinary goitre or for the exophthalmic form. Treves's Surgery makes no mention whatever of these symptoms, though it is stated without explanation that there is a considerable fatality attaching to operations for exophthalmic goitre. Turning to the original English papers to which I have been able to refer I find that two different views have been held on the subject, and I wish to show how far these cases support one of these views. It will be generally admitted from clinical experience that these symptoms to which I am drawing attention are particularly and specially connected with the thyroid gland. The dyspnœa is not at all like that of obstruction of the larynx or trachea. The rapid pulse and restlessness might suggest very severe hæmorrhage, but as a fact no hæmorrhage is found post mortem. The clinical picture is different from that of collapse after serious lesions of the abdomen; for example, perforation of a viscus into the peritoneum. Granting that these symptoms are intimately related to the thyroid gland we have next to inquire whether these symptoms are due to an excess of the thyroid secretion or whether they are due to a deficiency. Both these opinions have been held.

ANALOGY TO THYROID DISEASES.

Of known diseases connected with the thyroid gland we all recognise myxœdema, whether idiopathic or following total extirpation of the gland. Thanks to the researches of Gull, Ord, Kocher, Horsley, and others this disease has been clearly established as due to want of thyroid. But the apathy and dulness, the slow pulse and respiration of myxœdema bear no resemblance to the symptoms which may immediately follow a thyroid operation.
